# U. S. DEPARTMENT OF AGRICULTURE STATES RELATIONS SERVICE A. C. TRUE, DIRECTOR

EXPERIMENT STATION RECORD

# VOLUME XXXVII

JULY-DECEMBER, 1917

WASHINGTON GOVERNMENT PRINTING OFFICE 1918

# #1-9

U. S. DEPARTMENT OF AGRICULTURE.

Scientific Bureaus.

19/7 WEATHER BUREAU-C. F. Marvin, Chief.

BUREAU OF ANIMAL INDUSTRY-J. R. Mohler, Chief.

BUREAU OF PLANT INDUSTRY-W. A. Taylor, Chief.

FOREST SERVICE-H. S. Graves, Forester.

BUREAU OF SOILS-Milton Whitney, Chief.

BUREAU OF CHEMISTRY-C. L. Alsberg, Chief.

BUREAU OF CROP ESTIMATES-L. M. Estabrook, Statistician.

BUREAU OF ENTOMOLOGY-L. O. Howard, Entomologist.

BUREAU OF BIOLOGICAL SURVEY-E. W. Nelson, Chief.

OFFICE OF PUBLIC ROADS AND RURAL ENGINEERING—L. W. Page, Director.

BUREAU OF MARKETS-C. J. Brand, Chief.

STATES RELATIONS SERVICE—A. C. True, Director. OFFICE OF EXPERIMENT STATIONS—E. W. Allen, Chief.

# THE AGRICULTURAL EXPERIMENT STATIONS.

ALABAMA-

College Station: Auburn; J. F. Duggar.1

Canebrake Station: Uniontown; J. M. Burgess.1 Tuskegee Station: Tuskegee Institute; G. W. Carver.1

ALASKA-Sitka: C. C. Georgeson.2

ARKANSAS-Fayetteville: M. Nelson.1 California-Berkeley: T. F. Hunt.1

COLORADO-Fort Collins: C. P. Gillette.1

CONNECTICUT-

State Station: New Haven; E. H. Jenkins. Storrs Station: Storrs;

DELAWARE-Newark; H. Hayward.1

FLORIDA-Gainesville: P. H. Rolfs.1 GEORGIA-Experiment: J. D. Price.1

GUAM-Island of Guam: C. W. Edwards.2

HAWAII-

Federal Station: Honolulu; J. M. Westgate.2 Sugar Planters' Station: Honolulu; H. P. Agee1.

IDAHO-Moscow: J. S. Jones.1

Illinois- Urbana: E. Davenport.1 Indiana-La Fayette: C. G. Woodbury.1

IOWA-A mes: C. F. Curtiss.1

KANSAS-Manhattan: W. M. Jardine.1

KENTUCKY-Lexington: T. P. Cooper.1 LOUISIANA-

State Station: University Sta-

tion, Baton Rouge; Sugar Station: Audubon Park, W. R. Dodson.

North La. Station: Calhoun;

Rice Station: Crowley;

MAINE-Orono: C. D. Woods.1

MARYLAND-College Park: H. J. Patterson.1 MASSACHUSETTS-Amherst: W. P. Brooks.1

MICHIGAN-East Lansing: R. S. Shaw.1

MINNESOTA-University Farm, St. Paul: R. W. Thatcher.1

MISSISSIPPI-Agricultural College: E. R. Lloyd.1

MISSOURI-

College Station: Columbia; F. B. Mumford.1 Fruit Station: Mountain Grove; Paul Evans.1

MONTANA-Bozeman: F. B. Linfield.1

NEBRASKA-Lincoln: E. A. Burnett.1

NEVADA-Reno: S. B. Doten.1

NEW HAMPSHIRE-Durham: J. C. Kendall.1

NEW JERSEY-New Brunswick: J. G. Lipman,1 NEW MEXICO-State College: Fabian Garcia.1

NEW YORK-

State Station: Geneva; W. H. Jordan.1 Cornell Station: Ithaca; A. R. Mann.1

NORTH CAROLINA-Raleigh and West Raleigh: B.

W. Kilgore.1 NORTH DAKOTA-Agricultural College: L. Van Es.

OHIO- Wooster: C. E. Thorne.1

OKLAHOMA-Stillwater: H. G. Knight.1

OREGON-Corvallis: A. B. Cordley.1

PENNSYLVANIA-

State College: R. L. Watts.1

State College: Institute of Animal Nutrition: H. P. Armsby.1

PORTO RICO-

Federal Station: Mayaguez: D. W. May.3

Insular Station: Rio Piedras; E. Colón.1

RHODE ISLAND-Kingston: B. L. Hartwell.1 South Carolina-Clemson College: H. W. Barre. 1

SOUTH DAKOTA-Brookings: J. W. Wilson,1

TENNESSEE-Knozville: H. A. Morgan.1

TEXAS-College Station: B. Youngblood.1

UTAH-Logan: F. S. Harris.1

VERMONT-Burlington: J. L. Hills.1

VIRGINIA-

Blacksburg: A. W. Drinkard, jr.1

Norfolk: Truck Station; T. C. Johnson.1

WASHINGTON-Pullman: Geo. Severance.

WEST VIRGINIA - Morgantown: J. L. Coulter.1

Wisconsin-Madison: H. L. Russell.1

WYOMING-Laramie: A. D. Faville.1

<sup>1</sup> Director. <sup>2</sup> Agronomist in charge.

# EXPERIMENT STATION RECORD.

Editor: E. W. ALLEN, Ph. D., Chief, Office of Experiment Stations. Assistant Editor: H. L. KNIGHT.

### EDITORIAL DEPARTMENTS.

Agricultural Chemistry and Agrotechny-E. H. NOLLAU.

Meteorology Soils, and Fertilizers  $\left\{ egin{aligned} W.~H.~Beal. \\ R.~W.~Trullinger. \end{aligned} \right.$ 

Agricultural Botany, Bacteriology, and Plant Pathology W. H. Evans, Ph. D. W. E. Boyd.

 $\mathbf{Field\ Crops} \begin{cases} \mathbf{J.\ I.\ Schulte} \\ \mathbf{J.\ D.\ Luckett}. \end{cases}$ 

Horticulture and Forestry-E. J. Glasson. Economic Zoology and Entomology-W. A. HOOKER, D. V. M.

Foods and Human Nutrition (C. F. LANGWORTHY, Ph. D., D. Sc. H. L. LANG.

Zootechny, Dairying, and Dairy Farming D. W. MAY. M. D. MOORE.

Veterinary Medicine (W. A. HOOKER. E. H. NOLLAU.

Rural Engineering-R. W. TRULLINGER.

Rural Economics-E. MERRITT.

Agricultural Education (M. T. Spethmann.

Indexes-M. D. Moore.

# CONTENTS OF VOLUME XXXVII.

EDITORIAL NOTES.	
The response of the experiment stations to the present emergency	Page.
The adjustment of theory and practice to war conditions	4
Adequate station administration	101
Some tendencies under deficient administration	105
The Federal food production act	301
Research and the research worker in relation to national affairs.	401
The development of American technical agricultural journals	405
The Thirty-first Annual Convention of the Association of American Agricul-	
tural Colleges and Experiment Stations	601
Attendance at the agricultural colleges as affected by the war	701

Editorial notes:	Page.
The response of the experiment stations.	1
The adjustment of theory and practice to war conditions.  Recent work in agricultural science.	4 8
Notes	97
SUBJECT LIST OF ABSTRACTS.	
AGRICULTURAL CHEMISTRY—AGROTECHNY.	
Kafirin, protein from Andropogon sorghum, Johns and Brewster  Some proteins from the jack bean, Canavalia ensiformis, Jones and Johns  The proteins of the peanut.—I, Arachin and conarachin, Johns and Jones  The proteins of the colostrum and milk of the cow, Crowther and Raistrick  Protein copper compounds, Osborne and Leavenworth  d-Mannoketoheptose, a new sugar from the avocado, La Forge  A saponin from Yucca filamentosa, Chernoff, Viehoever, and Johns  Oxidase activity of plant juices and hydrogen ion concentrations, Bunzell  The sampling of fertilizers, Lodge  Influence of carbohydrates on accuracy of Van Slyke method, Hart and Sure  Estimation of mixtures of four or more carbohydrates, Wilson and Atkins  [Method for analysis of wheat grain, plants, and straw], Headden  New qualitative test and colorimetric method for estimation of vanillin, Estes  Summary of the composition of the wines of current consumption, Filaudeau  Adsorption of tin by proteins and the solution of tin by canned foods, Goss  The detection of added water in milk in India, Leather	8 8 8 8 8 9 9 9 9 10 10 11 11 12 12 13

	Dage
Nature of the reducing substances precipitated by lead subacetate, Pellet	Page.
Notes upon oil testing, Gill.  Color tests for oils.—Palm oil, Gill.  New method of steam distillation for volatile fatty acids, Dyer.  [Examination of lulu kernels and lulu oil (shea butter) from Uganda].  Estimating general turbidity of fluid suspensions, Dreyer and Gardner.  The estimation of amino-acid nitrogen in blood, Bock.  Concentration and rotatory power of solutions of nicotin, Tingle and Ferguson.  New method for determination of nicotin in tobacco, Tingle and Ferguson.  Sirups for canning and preserving, McNair.  The manufacture of apple jelly, Truelle.	13 13 14 14 14 14 14 15 15
METEOROLOGY.	
The quantitative study of climatic factors in relation to plant life, Adams.  World-wide changes of temperature, Brooks.  Improved methods in hygrometry, Shaw.  Department of meteorology. ## EXPERIMENT STATION RECORD.

Vol. 37. July, 1917. No. 1.

The response of men of science to the needs of the hour has been one of the striking features in the preparation for war. They have exhibited not only a desire for service but also a quick appreciation of what needed to be done and of the present dependence of a successful outcome upon the aid of science in many directions. It is doubtful if this exhibition has been paralleled in any other country or at any other time. We have had, of course, the example of European countries to suggest this dependence and point out directions in which the services of men of science were needed, and we have had the stimulating influence of nearly three years of war to arouse men to action. And fortunately we have had both the men and the institutions. The latter, especially, have felt the call very keenly. The institutions of the whole country have come forward with a splendid spirit of service, and represent a breadth and resourcefulness which already are recognized as a powerful asset.

In this prompt response the land-grant colleges have stood out conspicuously. They have shown that they were not only willing but ready. They have realized the occasion as their great opportunity, as it was their duty under their Federal charter. Their initiative and leadership have been a striking illustration of the value of these institutions to the country, and of the kind of training they offer. Students have gone from the classroom to the officers' training camps and into various forms of agricultural service in such numbers as to reduce the attendance to one-third or a quarter or even less; and many of the colleges cut their spring terms short to release students and faculty. The agricultural extension service has become a chief reliance and assumed paramount importance in stimulating production, locating supplies, and giving personal aid and instruction to farmers, amateur gardeners, boys' and girls' clubs, and women of the town and country.

And back of it all, the experiment stations have continued their quiet but effective work, shaping it where necessary to the present emergency, speeding it up in other cases, and in general making their results and practical suggestions the basis of action by the public. Because their efforts often keep them in the background where their

work lies, and does not bring them so prominently into evidence as the teacher who is before the public, they should not be overlooked or their vital importance forgotten. It is in very large measure their work which has made it possible to meet promptly the present emergency, by building upon the teachings of investigation and experiment throughout the whole gamut of agricultural production, protection, utilization, and preservation. We can hardly comprehend how different the task would have been twenty-five years ago. There is hardly a phase, even a local one, which their work has not touched and is not now being realized upon.

But this does not mean that we have touched bottom in all there is to know or all there is need to know to meet a sudden crisis. The foresight and insight, the resources and ingenuity, of the experiment stations and all agencies for research should be drawn upon as they never have been before. It will rest largely with them to anticipate the needs for dependable information and to forestall these needs by setting the necessary studies in operation. This means working close to the ground, with a keen eye to the emergency and the measures for meeting it. Never was it more important for the experiment station forces to be alert to the whole agricultural situation, to see with the eyes of experts, and weigh suggestion on the broad basis of relationships as well as of necessity.

It is gratifying to learn definitely, through word received from a considerable number of the stations, that they are fully alive to the situation and have already set their plans in motion. In a number of cases the directors are occupying prominent positions on the State councils of defense, and in others the stations are cooperating actively with these councils in agricultural matters and food supply. At several of the agricultural colleges and experiment stations war emergency committees have been formed to review the projects in hand and outline suggestions regarding special emergency investigations. To a notable extent such studies of more immediate importance have been started, replacing in some degree those which can be postponed until a later time. Thus a majority of the stations already are operating more or less under a war-time program.

In addition to these new undertakings, it is interesting to note the large amount of work in progress before the declaration of war which fits well into the new program. This is shown by a review of the stations' projects and an examination of their work in the field. It emphasizes anew the practical character of their studies and demonstrates their place in the present emergency.

For example, one of the measures advocated to increase food production is the more extensive cultivation of legumes, like soy bean, velvet bean, and the peanut, to be used either as pasturage, for ensiling with corn, or for grinding as stock feed. This gives quite

a variety of products, especially when there is added the residues from oil extraction, the value, utilization and effect of which products have not been well known. The stations in the South have anticipated the need for such information, and during the past year especially have made many field and feeding experiments of various kinds.

It was found, for example, that peanuts and soy beans make a soft pork and lard, and that hogs fed extensively on these products are of less value to the packinghouses. Numerous experiments show the extent to which these materials may be fed, the amount of other feeds necessary to harden the pork, and the period over which they must be fed to accomplish this. Already probably sufficient data are on hand to answer many of these leading questions if they could be

brought together and digested.

The increase of pork production is advised as an important means of maintaining meat supply. Successions of forage crops for pasturing hogs throughout the year have been worked upon at several of the stations, which give relatively cheap products. Waste products, especially those on farms, will need to be utilized to a larger extent to piece out and economize the feed supply. This has been a subject of much experimentation, in all parts of the country. The ordinary materials include such as corn stalks, cotton stalks, straw, waste hay, and aftergrowth in cultivated fields. The wintering in good condition, at one station, of a lot of fifty-eight steers on the hay cut from a corn stalk field containing pea vines, Johnson grass. crab grass, etc., which grew up after the corn had been pulled, emphasizes the possibility of utilizing to advantage roughage which would otherwise be practically wasted. Experiments with steers and with sheep on dry-land feeds show how far these materials may be relied upon, and in the case of sheep demonstrate the advantage to farmers of having a sufficient number to eat up the roughage and waste instead of keeping them all on the range.

No less than ten different stations have lately been working on various aspects of the conservation, handling, and most efficient use of barnyard manure—a subject of prime importance at a time when there is a shortage of fertilizers and difficulty in securing potash. That so many stations still regard the subject as a fruitful one for study is strong indication of the possibilities for constructive work outside the field of propaganda and demonstration. Indeed, there is not yet full agreement on the theory of the beneficial action of this

material, or how it may be further extended.

Increase of the acre-yield of wheat is one of the direct ways of increasing the volume of production. The means for this have been the subject of continued study and experiment the country over, the larger application of which has awaited just such conditions as the

present affords. The working of these results into the practice of wheat growing is not altogether a matter of bulletins and propaganda. The Ohio Station recognizes this in its call to farmers to attend its "wheat field meetings," and join in the slogan "Sixty million bushels of wheat for Ohio in 1918." Its circular says: "For a third of a century the Ohio Experiment Station has been preparing for this emergency, and its wheat fields, scattered over the State as they are, are in condition to show both what to avoid and what to do in order to produce a maximum crop of wheat on Ohio soil."

Another station has just completed an extensive study of the rice weevil and the method of preventing the immense injury it does to corn stored on farms. This control is based on simple, practicable methods of harvesting and storing the crop, which it is confidently asserted would save some three million dollars' worth of corn in Alabama alone. The ensiling of the fodder would help to keep down the weevil and at the same time add further to the value of the crop.

Illustrations could be multiplied without end. The important thing is that the results should be put out promptly, and preferably summarized so that they will be more readily available to extension workers and farmers over a wide area.

With a view to stimulating experiment and investigation along the lines of the present need, the Agriculture Committee of the National Research Council has undertaken to formulate suggestions and serve as an agency in arranging for cooperation or coordinated effort. This committee is a representative one, covering in a general way the whole field of agricultural investigation, and will be assisted by the Office of Experiment Stations in inaugurating its plans.

From the relation of the National Research Council to the Council of National Defense, it is in position to view broadly the special needs of investigation and offer suggestions for work which will be timely. Through this Office the cooperation of the experiment stations in this undertaking has been invited, and they will be asked to participate in conducting specific inquiries.

It will be clear that the occasion offers unusual opportunity for cooperation among the experiment stations, which will be one of the chief agencies in providing new information at this time. The situation also makes extremely desirable a larger measure of coordination of effort than ordinarily exists. Concerted action on topics which are urgent will be more effective and yield quicker returns than isolated individual effort conducted without knowledge of a general plan.

Information as to emergency investigations already in progress at different stations will prevent an unnecessary amount of duplication and thus serve to conserve effort; and on the other hand, suggestions

as to subjects upon which investigation is deemed necessary will enable participation in a constructive plan aimed to advance the common cause. Such suggestions coming from a central committee in close contact with the Council of National Defense will naturally carry an unusual appeal.

In a new sense the present problem of agricultural production is a national one, in which the whole country and even the Allies of Europe are deeply concerned. Hence the measures to accomplish that end justify an unusual measure of coordination, which may extend properly to the investigation conducted at the experiment stations. Never was it more important to demonstrate the capacity of station workers to unite for cooperative or coordinated effort and their willingness to subordinate the individual in measures for the common good.

The research workers and experimenters are to agricultural production what the information service and the strategic branch are to the military forces. An effective dash can be made on what we already know, but in any protracted contest new information and new resources will often be needed to meet the requirements, and especially to adapt what we know to war-time conditions. The latter are so different and in a sense abnormal as to warrant practices not ordinarily employed, and require special experiments to be made. Continued warfare naturally tends to make agricultural production less effective because of the drains it makes on men, on live stock, on supplies like seed, fertilizers, and spray material, and the increasing difficulties of distribution. If our live stock is to remain undepleted, except through the intelligent weeding out of the drones, weaklings, and unproductive individuals, there must be provision for using more of the waste of farms, growing leguminous feeds without displacing the cereal acreage, an economy of protein, and a utilization of feeds of all kinds to the best possible advantage.

In time of stress there is less warrant for the outlay of feed to produce ideal fattening or a high degree of finish in meat animals. From the large amount of experimental data secured by a number of the stations, in the Central West especially, it ought to be possible to deduce simple, cheap methods for meat production suited to the needs of the hour, even though they give less fancy products.

To a certain extent the potash question is an emergency problem, as are others connected with the provision of necessary fertilizing materials. But the solution of the potash problem lies in determining the economy of potash and where the actual necessity for it lies in agriculture, as well as in increasing the supplies.

At this time, especially, there is the large question of how to cut down hand work and increase the man power so as to make it more productive in the face of labor shortage. The tractor problems are

not all solved, either in their mechanical or economic aspects, and there is still opportunity for the agricultural engineer to point out the place of these machines and their weaknesses.

The furnishing of a billion bushels of wheat and other cereals to the European Allies, as is estimated to be required, will call for a large saving in the consumption of cereals and corn in this country. This will have to be effected by the partial substitution of corn for wheat as human food, and a corresponding saving in the corn fed to live stock. The latter ordinarily represents over three-fourths of the entire corn crop. To accomplish this saving of corn and still feed the same live stock will call for the use of other feeds in its place.

How far this chain of readjustment may reach is illustrated, for example, by the simple case of a proposal to save for feed the large amounts of wheat bran now used in the process of making tin plate. The bran is employed to take up the excess of oil applied to the plate to prevent corrosion, and this use renders it unfit for feed. An effort has been started to substitute ground peanut hulls for this purpose, the provision of which will involve an adjustment of practice at some of the oil mills handling peanuts.

The large underlying questions connected with meeting the present demand on American agriculture furnish the problems for the experiment stations. Many of these are relatively elementary and to a certain extent local, some of them verging on experimental demonstration, while others involve more extended and profound inquiry. The wisdom or feasibility of undertaking such inquiries may be questioned by some on the score of time; but if there is time and it is feasible to build a large fleet of vessels for transporting the world's commerce, there is time and it is expedient to set in motion a body of inquiry and experiment specially suggested by the wartime needs of agriculture. This inquiry, like the ships, will be useful and will be needed even though peace should come before they are completed.

The emergency provides a special opportunity for effecting radical and farreaching changes in our agriculture based on experimental knowledge, which it would otherwise require many years to bring about. It is well, therefore, to plan carefully, with the agricultural conditions and the need of permanent as well as temporary improvement clearly in mind. And the program made need not be dependent wholly on the time element as measured by the probable duration of the war. Never has there been such an opportunity to secure the acceptance of sound practical science in agriculture; and beyond helping to save the day through increased production, the experiment

stations may aid in bringing about many radical changes in the art which will be of permanent character.

It is hardly necessary to caution that the attempt to meet emergency conditions should not result in the abandonment of fundamental investigations already in progress and which would suffer from interruption. It is highly important to protect our institutions and machinery for research. The war has dealt a severe blow to those of Europe and greatly interfered with the progress of scientific work. Many of the workers of outstanding ability have taken part in the conflict and sacrificed their lives to it. The progress of agricultural investigation, along with other branches, has thus been handicapped to a degree which will long be felt.

The foreign literature relating to agricultural research has very materially diminished, and much of what remains has taken on a war emergency flavor. The publications of this Department and the experiment stations, on the other hand, have greatly increased in volume. Our literature has been made use of in meeting the crisis abroad, and our work will find application there later. It may be one of America's responsibilities to keep alive the lines of research in agriculture which were sprouted on European soil, and to add to the store the product of new fundamental inquiries which by reason of dealing with the principles of science will have world-wide application.

## RECENT WORK IN AGRICULTURAL SCIENCE.

#### AGRICULTURAL CHEMISTRY-AGROTECHNY.

Kafirin, an alcohol-soluble protein from Kafir, Andropogon sorghum, C. O. Johns and J. F. Brewster (Jour. Biol. Chem., 28 (1916), No. 1, pp. 59-65).—The authors have isolated from Kafir corn seeds a new alcohol-soluble (kafirin) protein which constitutes more than one-half of the protein of the seed. The new protein is similar to zein in its ultimate composition, but differs in physical properties. Analysis showed it to contain both tryptophan and lysin.

The experimental data are described in detail.

Some proteins from the jack bean, Canavalia ensiformis, D. B. Jones and C. O. Johns (Jour. Biol. Chem., 28 (1916), No. 1, pp. 67-75).—Two globulins, canavalin and concanavalin, and an albumin similar to legumelin have been isolated from the bean. The percentage distribution of nitrogen in the albumin was as follows: Humin, 0.23; amid, 1.16; basic, 3.73; and nonbasic, 11.18. In canavalin the following percentage distribution was obtained: Humin, 0.28; amid, 1.41; basic, 3.17; and nonbasic, 11.55.

The proteins of the peanut, Arachis hypoge.—I, The globulins arachin and conarachin, C. O. Johns and D. B. Jones (Jour. Biol. Chem., 28 (1916), No. 1, pp. 77-87).—Two globulins, designated by the authors as arachin and conarachin, have been isolated from the peanut. Arachin was found to contain 0.4 per cent sulphur and 4.96 per cent basic nitrogen; conarachin, 1.09 per cent sulphur and 6.55 per cent basic nitrogen, the latter being the highest percentage of basic nitrogen recorded for any seed protein.

From the analytical results it is deemed probable that peanut press cake will prove to be of value in supplementing food products made from cereals and other seeds deficient in basic amino acids. It is indicated that feeding experiments to determine the nutritive value of combinations of peanut proteins with other proteins are in progress

A comparative study of the proteins of the colostrum and milk of the cow and their relations to serum proteins, C. Crowther and H. Raistrick (Biochem. Jour., 10 (1916), No. 3. pp. 434-452).—Detailed analytical data obtained by the application of the Van Slyke procedure (E. S. R., 26, p. 22) to the proteins of cow colostrum and cow's milk show that caseinogen, total lactoglobulin, and lactalbumin are sharply differentiated, distinct proteins and have respectively the same compositions whether prepared from colostrum or normal milk. Eulactoglobulin and pseudolactoglobulin are identical so far as the protein part of their molecule is concerned. The presence of the globulin in very small quantities in milk was proved.

Lactoglobulin from either colostrum or milk was found to be very closely allied to and probably identical with serum globulin from ox blood. Lactal-bumin from either colostrum or milk, however, was found to be very different in composition from the serum albumin of ox blood.

Protein copper compounds, T. B. OSBORNE and C. S. LEAVENWORTH (Jour. Biol. Chem., 28 (1916), No. 1, pp. 109-123).—The authors report in detail the

results of experiments on the preparation of copper compounds of edestin and gliadin. The probable structure of these complex compounds and the significance of such data as submitted are briefly discussed.

**d-Mannoketoheptose**, a new sugar from the avocado, F. B. La Forge (*Jour. Biol. Chem.*, 28 (1917), No. 2, pp. 511-522).—The isolation of the sugar and its chemical properties are described in detail.

A saponin from Yucca filamentosa, L. H. CHERNOFF, A. VIEHOEVER, and C. O. Johns (Jour. Biol. Chem., 28 (1917), No. 2, pp. 437-443).—A new saponin (C<sub>24</sub>H<sub>40</sub>O<sub>14</sub>) has been isolated from the root stock of Y. filamentosa, a yield of the crude saponin of about 6 per cent being obtained. The material is soluble in water, alcohol, phenol, and glacial acetic acid, but can not be precipitated from aqueous solution by neutral or basic lead acetate and barium hydroxid. No cholesterol compound could be prepared. Hemolysis of rabbit blood was observed after 15 minutes in the saponin solution at 37° C.

Hydrolysis yielded a sapogenin which crystallized in regular, fine needles, melting at 175°. The molecular weight of this material was approximately 255. It was soluble in alcohol, phenol, and glacial acetic acid, but not in alkall or dilute acids. The crystals of this material showed practically no bemolytic action. A sugar identified as glucose was also obtained on hydrolysis. The evidence indicated that glucuronic acid is formed during the hydrolysis.

The saponin is located as a brownish amorphous mass in the fibro-vascular bundles in the roots and leaf bases.

The relationship existing between the oxidase activity of plant juices and their hydrogen ion concentrations, with a note on the cause of oxidase activity in plant tissues, H. H. Bunzell (Jour. Biol. Chem., 28 (1916), No. 1, pp. 315-333, figs. 3).—Experimental data on the oxidase activity of potato peel powder (1915); potato peel powder (1916); potato sprouts; scaled tulip tree buds and tulip tree leaves (1916); tulip tree leaves (1915); magnolia leaves and flower petals (1915); and magnolia leaves, flower petals, and stamens from these flowers (1916) under varying hydrogen ion concentrations are reported in detail and the results discussed.

The results corroborate in a quantitative way the findings of earlier investigators on the inhibition of oxidase activity by acids. For the potato material the inhibiting hydrogen ion concentration ranged from 3.55 to 3.7. For the tulip tree material (scaled buds, scales, or leaves) the range was between 2.3 and 2.8. In the magnolia the range was from 2.45 to 3.05. These results seem to indicate "that the sensitiveness to acidity of all the oxidase factors throughout the same plant is approximately uniform; moreover, since different specimens of the same genus collected at different times of the year were used, it would indicate also that the acid sensitiveness figure is a rather fixed number, characteristic for any particular genus. It would even seem that the acid sensitiveness constant is the same or nearly the same for different genera (tulip tree and magnolia) of the same family (Magnoliaceæ)."

The material responsible for the phenomena of oxidase activity thus appeared to be identical in closely related plants.

The experiments are considered not to be exhaustive. See also a previous note by Reed (E. S. R., 36, p. 503).

The sampling of fertilizers, F. S. Lodge (Jour. Indus. and Engin. Chem., 9 (1917), No. 2, pp. 167-169, fig. 1).—This is a general discussion of the various types of samplers used throughout the country in the control of fertilizing materials. The lack of uniformity in samplers and the difficulty of securing a representative sample by most of the samplers used is pointed out.

The sampler considered to meet all conditions best is one which was designed at the Indiana Experiment Station, and consists of two telescoping

slotted brass tubes terminating in a solid pointed end. The sampler can be inserted to the full length of the bag before any material can enter the sample chamber. As representative a sample of the material as is practically possible is thus obtained.

The necessity of drafting standard methods for sampling fertilizers and the recognition of such methods as official is indicated.

The influence of carbohydrates on the accuracy of the Van Slyke method in the hydrolysis of casein, E. B. Hart and B. Sure (Jour. Biol. Chem., 28 (1916), No. 1, pp. 241-249).—Experimental data obtained from hydrolysis and amino-acid nitrogen distribution determination according to the Van Slyke procedure (E. S. R., 26, p. 22) for pure casein and casein with dextrose, sucrose, starch, and xylan, respectively, are reported in tabular form.

The results indicate that the presence of these carbohydrates during the hydrolysis brings about a total redistribution of the amino acids, varying with the nature of the carbohydrate employed. Marked changes were especially apparent in the hexone bases and a decided loss of nonamino nitrogen occurred in the presence of xylan.

The authors conclude from the results of Gortner (E. S. R., 36, p. 108) and the present results submitted that the method of direct hydrolysis for the estimation of amino acids in feeding stuffs by Van Slyke's method is inapplicable, and that the results so secured will be inaccurate. The use of factors is deemed to be impossible because of the variation of the nature and quantity of the carbohydrates in feeding stuffs, and because of this variation the results obtained are not even of comparative value.

It is further concluded that "in the present unsatisfactory status of the methods for estimating the amino acids in the complex protein-carbohydrate mixture of feeding stuffs the only reliable procedure for obtaining an insight into the nutritive worth of the proteins in such a mixture will be the biological one."

Methods for the estimation of mixtures of four or more carbohydrates, involving oxidation with bromin, Edith G. Wilson and W. R. G. Atkins (Biochem. Jour., 10 (1916), No. 3, pp. 504-521, fig. 1).—Analytical data submitted and discussed show that glucose and maltose are quantitatively oxidized by bromin at room temperature when allowed to stand in a saturated solution. Fructose is not oxidized at all or only to a very small extent by bromin under these conditions. In the presence of tenth-normal sulphuric acid there is slight loss of fructose in 66 hours at room temperature.

For the analysis of a mixture of sucrose, maltose, glucose, and fructose the following scheme is described: The sucrose is determined by polarization and reduction before and after treatment with invertase. The resulting mixture of reducing sugars is treated with bromin under standard conditions of acidity and temperature, by which the aldehydic sugars, glucose and maltose, are oxidized. The ketonic sugar remains behind. The reducing power of the solution may then be taken as due to fructose alone. The rotations due to the fructose and sucrose are then allowed for in the initially determined rotation. This gives the rotation due to glucose and maltose. The reduction due to fructose is subtracted from the initial reduction, which thus gives the reduction due to glucose and maltose. From these data equations can be constructed for determining the amounts of the two remaining sugars.

It is indicated that the addition of dilute alkali to a solution of glucose. fructose, or maltose produces a large temporary increase in its reducing power. The necessity of keeping solutions neutral or very faintly acid in analytical work is obvious. Some indication has been obtained of the formation of a

compound between sodium hydroxid and glucose from a study of the electrical conductivity of such a mixture.

An attempt to modify Barfoed's solution for quantitative work was unsuccessful.

[Methods for analysis of wheat grain, plants, and straw], W. P. HEADDEN (Colorado Sta. Bul. 219 (1916), pp. 124-127).—The following procedures were used in the study noted on page 38.

For oxidizing the wheat grain 25-gm. samples were treated with concentrated nitric acid in separate portions of from 15 to 20 cc. The material foams strongly and care must be taken that none is lost during the oxidation. Silica dishes were used, but it was found that small flakes sometimes broke off and were weighed as silica. The amount, however, was usually extremely small and negligible. When 50 cc. of nitric acid had been added the residue was evaporated to a gummy mass and charred over a free flame, and finally heated in the muffler. To remove the small portion of carbon remaining the mass was treated with aqua regia, the solution evaporated to dryness, the residue treated with hydrochloric acid, and filtered. The filter which contained the residual carbon and silica was returned to the dish, burned, and treated as before. In the solution of the ash, the iron, calcium and magnesium were precipitated as phosphates, the iron weighed as phosphate, the calcium as oxid, and the magnesium as pyrophosphate.

The filtrate which contained the alkalis was concentrated and acidulated with hydrochloric acid if necessary, an excess of ferric chlorid was added, and then ammonia in excess to precipitate the ferric oxid and with it the phosphoric acid. The precipitate was filtered off, washed, dissolved in hydrochloric acid, and again reprecipitated. The united filtrates contained the alkalis as chlorids and were treated in the usual manner.

The chlorin was determined in a separate 10-gm. sample which was dissolved in a mixture of nitric acid and silver nitrate. When completely dissolved, water was added, which increased the bulk of the white flocculent precipitate of silver chlorid. It was filtered off, washed, the mass mixed with a mixture of potassium nitrate and sodium carbonate, transferred to a nickel dish containing 2 or 3 gm. of the nitrate-carbonate mixture, the mass covered with the mixture, and heated until completely fused. The fused material was dissolved in water and the usual determination for chlorin followed.

The phosphorus was determined in a 10-gm. sample which was dissolved in concentrated nitric acid, after which 1.5 gm. of magnesium oxid was added and the whole evaporated to a brown, gummy mass, and ignited. The cooled mass was treated with dilute nitric acid, evaporated again, and the combustion completed. It was then dissolved in nitric acid, evaporated with sulphuric acid to separate silica, and the phosphoric acid precipitated as molybdate and finally weighed as magnesium pyrophosphate.

The sulphur was determined in a manner similar to the phosphorus determination, except that ordinary gas could not be used during the oxidation.

The manganese was determined colorimetrically and the samples oxidized and ashed by means of nitric acid as in the other procedures. The combustion was completed in the muffler and the residue taken up with sulphuric acid and filtered. The solution should contain about 5 per cent sulphuric acid. A few milligrams of silver sulphate and a few grams of ammonium persulphate were added and the solution heated until the color had developed completely.

Some difficulties were experienced in determining the ash of the wheat plant and wheat straw. For the ash determination 10 gm. of the ground straw or plant was thoroughly charred and extracted three times with boiling water.

The carbon was then burned out as completely as possible, again thoroughly extracted with water, and the residue finally ignited and weighed as insoluble ash.

For the analysis proper 100 gm. of the ground straw was taken and treated as noted above. The charred mass was extracted, however, with hydrochloric acid and after filtration the carbon burned out as far as possible, and the residue again extracted with hydrochloric acid and then ignited and considered as pure silica. The hydrochloric acid extracts were evaporated to dryness to separate the soluble silicic acid, and the weight of the silicic acid thus obtained added to the insoluble silica to obtain the total silica. The hydrochloric acid solution was made up to 250 cc. and aliquots taken for further determinations by the procedures used for the wheat grain. The phosphorus was determined in a separate 25 gm. sample which was treated with nitric acid and magnesium oxid. The thoroughly burned mass was dissolved in nitric acid and a few cubic centimeters of concentrated sulphuric acid added, and evaporated until sulphuric acid fumes were given off, after which the dish was placed in a hot-air oven and kept at 160° C., or higher, to allow the separation of the silicic acid. The phosphoric acid was then determined by the usual procedure of precipitation by ammonium molybdate, and finally weighed as magnesium pyrophosphate. If necessary, the silicic acid could be removed by hydrofluoric acid before the addition of the magnesium oxid.

The sulphur was determined in the same manner as in the wheat grain. The same procedure was also used for the determination of manganese, except that the silica was removed by concentrated hydrofluoric acid.

A new qualitative test and colorimetric method for the estimation of vanillin, C. Estes (Jour. Indus. and Engin. Chem., 9 (1917), No. 2, pp. 142-144).—After some preliminary experimentation the author devised a procedure for the determination of vanillin which depends on the production of a violet to violet-red color when a solution of vanillin is treated with an acid solution of mercuric nitrate.

The procedure as applied to alcoholic extracts is as follows: To 5 cc. of the extract in a 50-cc. graduated flask, 6 cc. of water and 1.5 cc. of the acid mercuric nitrate reagent are added. The standard is made up at the same time with 5 cc. of the standard vanillin solution, 0.5 cc. of the reagent, and 6 cc. of water. The two flasks are placed in boiling water for 20 minutes. They are then taken out, rapidly cooled, made up to the mark, filtered, and the colors compared.

For nonalcoholic extracts the standard is prepared in the same way as for alcoholic extracts, and the only change in the preparation of the unknown is the quantity of reagent used, 1 cc. having been found to give the maximum intensity of color.

Analytical data submitted indicate that the results obtained on commercial vanilla extracts agree very closely with those from the gravimetric procedure.

Summary of the composition of the wines of current consumption, G. FILAUDEAU (Ann. Falsif., 9 (1916), No. 96, pp. 347-418).—These pages contain detailed tabular analytical data of the various wines of the harvest of 1915, together with comments on the data.

Adsorption of tin by proteins and its relation to the solution of tin by canned foods, B. C. Goss (Jour. Indus. and Engin. Chem., 9 (1917), No. 2, pp. 144-148).—The work reported shows that "the solution of tin by canned foods is neither dependent upon, nor proportional to, the acidity alone, and, also, that in the foods of relatively slight acidity which dissolve large amounts of tin the greater part of the tin is in the form of an insoluble and stable complex." The data indicate that the phenomena are due to adsorption, and that the tin,

after being dissolved from the lining of the can, is continually removed from solution by the proteins, carbohydrates, and other highly porous solid phases in contact with the solution. The theory in regard to the adsorption of the tin ions is discussed.

The seeds of red cherries, black cherries, black raspberries, strawberries, and tomatoes were found to have adsorbed quantities of tin far in excess of the tin found in solution. The physiological significance of this adsorption of the tin by the seeds is indicated, since the seeds are usually eliminated intact. It is also noted that "it would appear that the amount of soluble tin salts, rather than the total tin present in a can of food, should be limited, since it is the part of the tin adsorbed which determines the physiological action."

The detection of added water in milk in India, J. W. Leather (Agr. Research Inst. Pusa Bul. 57 (1915), pp. 7).—Using the procedure described by Beckmann (E. S. R., 6, p. 611), with some slight modifications, the author determined the freezing point of milks of Indian cows and buffaloes, and from the data has evolved a formula for determining the percentage of added water by this procedure. A table showing the percentage of added water corresponding to the freezing point of the sample, ranging from —0.542° to —0.247° C., is included.

The nature of the reducing substances precipitated by lead subacetate in the defecation of impure sugar solutions, H. Pellet (Ann. Chim. Analyt., 21 (1916), No. 11, pp. 217-223).—The author briefly reviews previous studies of the precipitate produced by defecation with lead subacetate, and from the results, together with his own experience, concludes that its use is unsatisfactory.

The use of normal lead acetate (30 per cent solution) and the removal of the excess lead with a saturated solution of sodium carbonate is recommended as being entirely satisfactory for defecation in the determination of reducing sugars in cane products, foods, diabetic urine, etc.

Notes upon oil testing, A. H. GILL (Jour. Indus. and Engin. Chem., 9 (1917), No. 2, p. 136).—A test for oils by salting out their soaps is described, and some analytical data, expressed in grams of sodium chlorid per gram of oil, for several oils, a sample of oleomargarin, and a sample of butter are submitted. A test for gelatinous matter in linseed oils and its use are also described.

Color tests for oils.—Palm oil, A. H. GILL (Jour. Indus. and Engin. Chem., 9 (1917), No. 2, pp. 136-139).—The Halphen and Becchi tests for cottonseed oil, the Baudouin test for sesame oil, the Liebermann-Storch test for rosin oil, and the Crampton-Simons test for palm oil are briefly discussed and some analytical data on the Crampton-Simons test submitted.

From the data the test is considered to be no longer available for use in connection with the testing of oleomargarin (to determine the presence of palm oil) because of its unreliability, due to the difficulty in interpretation. The test is one for carotin rather than palm oil and may be given by butter, oleo oil, or sesame oil, ingredients ordinarily found in oleomargarin. As commonly applied, it is also untrustworthy on account of the presence of interfering oils, as sesame, which are not washed out.

The work reported is considered preliminary and the subject is being further studied.

A new method of steam distillation for the determination of the volatile fatty acids, including a series of colorimetric qualitative reactions for their identification, D. C. Dyer (Jour. Biol. Chem., 28 (1917), No. 2, pp. 445-473, pl. 1, flg. 1).—A method of steam distillation for the determination of volatile fatty acids, which depends on the maintenance of the aqueous solution containing the acids at a constant volume throughout the course of the distillation,

is described. The distilling constants of the individual volatile fatty acids have been determined and are represented graphically by straight lines on a logarithmic chart, while the distilling variables of mixtures are indicated by curved lines. The calculations necessary for determining the amounts of the various acids in a mixture are described in detail.

Some qualitative tests for the identification of various acids in a mixture, together with a simple and convenient apparatus for maintaining a constant volume during the distillation, are described in detail.

[Examination of lulu kernels and lulu oil (shea butter) from Uganda] (Ann. Rpt. Dept. Agr. Uganda, 1916, pp. 59-61).—Analytical data of a sample of lulu kernels and of two samples of butter made from the oil of the kernels are submitted.

A general method of estimating the general turbidity or opacity of fluid suspensions including bacterial emulsions, G. Dreyer and A. D. Gardner (Biochem. Jour., 10 (1916), No. 3, pp. 399-407, fig. 1).—A simple and accurate method for measuring the turbidity of two fluids and its special application to the standardization of agglutinable cultures is described in detail. The procedure is indicated as being applicable to all chemical and biological investigations which require turbidity measurements.

The estimation of amino-acid nitrogen in blood, J. C. Bock (Jour. Biol. Chem., 28 (1917), No. 2, pp. 357-368).—Experimental data submitted indicate that the use of alcohol as a protein precipitant in the determination of amino nitrogen in blood, as recommended by Van Slyke and Meyer. is undesirable. A comparative study indicates that the use of trichloroacetic acid as introduced by Greenwald is very serviceable, and a slight modification of the procedure is described. Coagulation of the blood at boiling temperature in a weakly acid solution was found not to increase the filtrate nitrogen provided the traces of protein which escaped coagulation were properly removed.

Factors connecting the concentration and the optical rotatory power of aqueous solutions of nicotin, A Tingle and A. A. Ferguson (*Proc. and Trans. Roy. Soc. Canada, 3. ser., 10 (1916), Sect. III, pp. 19-25).*—Experimental data on the influence of dilution on the rotatory power of aqueous nicotin solutions, the effect of free alkali and alkali salts on the rotatory power of nicotin solutions, effect of evaporation in the presence of sulphuric acid, and the preparation of pure nicotin are reported.

The results show that for concentrations between 4 per cent and 0.37 per cent the rotatory power of an aqueous solution of nicotin is strictly proportional to its concentration. Repeated evaporation with sulphuric acid in small excess did not cause any change in the rotatory power of nicotin, nor did the presence of free caustic alkali or salts of the alkaline metals cause any change in the rotatory power of such solutions. The rotatory power of nicotin in water was found to be such that, examined in a 200 mm, tube, 1 gm, of nicotin in 100 cc. of solution would give a negative rotation of 4.5 divisions on the Ventzke sugar scale, or conversely a negative rotation of 1 division would correspond to 0.2198 gm, of nicotin in 100 cc.

A new method for the determination of nicotin in tobacco, A. TINGLE and A. A. FERGUSON (Proc. and Trans. Roy. Soc. Canada, 3. ser., 10 (1916), Sect. III, pp. 27-31).—A polarimetric method which depends on the assumptions that the rotatory power of a solution of nicotin in water is not changed by the presence of alkalis or salts of alkalis in the solution, that the acid solutions of nicotin sulphate may be evaporated without either loss by vaporization

<sup>1</sup> Jour. Biol. Chem., 12 (1912), No. 3, pp. 399-410.

<sup>&</sup>lt;sup>9</sup> Jour. Biol. Chem., 21 (1915), No. 1, pp. 61-68.

or racemization, and that the rotatory power of an aqueous solution of nicotin containing 3 per cent of the base or less is proportional to its concentration, is proposed.

The procedure described consists of distilling the nicotin with barium hydroxid by a current of steam, acidifying the distillate with sulphuric acid, and then evaporating to about 50 cc. volume. The concentrated solution is made to volume and then made strongly alkaiine with concentrated KOH followed by a few drops of barium hydroxid. This last addition is not essential, but tends to clarify the solution when any turbidity is developed. The liquid is again made to volume, the precipitate allowed to settle, and, after filtering the supernatant liquid, the filtrate is examined in a polarimeter. The calculations for the amount of nicotin present from the polarimetric readings are described.

A slightly modified procedure in which the distillate is not acidified, but extracted with chloroform and the chloroform extracts treated with sulphuric acid in a separatory funnel is also described. After heating to expel the dissolved chloroform the solution is made alkaline with KOH and the filtrate then examined polarimetrically.

The method yields higher results and is considered to be more accurate than the Kissling procedure, which is official.

Sirups for canning and preserving, J. B. McNair (Jour. Indus. and Engin. Chem., 9 (1917), No. 2, pp. 151-153, fig. 1).—Tables showing number of the gallons of water or ounces of sugar per gallon of sirup required to change a sirup from a given degree Brix to another given degree Brix at 17° C., changes in volume (in parts per 10.000) of sirups at different temperatures, and the correction for the readings of Balling's saccharimeter on account of temperature are submitted and their use described.

The value of such data in connection with the preparation of fruit jellies is indicated.

The manufacture of apple jelly, A. Truelle (Vie Agr. et Rurale, 6 (1916), No. 46, pp. 357-361, figs. 2).—This is a general discussion of English methods of preparation, together with the results of some original experiments by the author.

A table giving the grams of acid (as malic), tannin, and pectin in 100 cc. of the juice of 50 varieties of apples is included.

#### METEOROLOGY.

The quantitative study of climatic factors in relation to plant life, J. ADAMS (Proc. and Trans. Roy. Soc. Canada, 3. ser., 10 (1916), Sect. IV, pp. 105-123).—This article discusses the relations of temperature, light, precipitation, evaporation, and wind to plant growth at various places in Canada and makes certain general deductions as to such relationships.

World-wide changes of temperature, C. F. Brooks (Sci. Amer. Sup., 83 (1917), No. 2152, pp. 194, 195; Geogr. Rev., 2 (1916), No. 4, pp. 249-255).—This article deals primarily with the possibility of seasonal forecasts. It is stated that "the weather in widely separated parts of the earth is correlated because of the extensive control of the large belts and centers of atmospheric action. . . . These are subsequent, however, to changes in the sun's radiation, which produce immediate, world-wide pressure alterations. Any possibilities for widespread seasonal forecasts must rest, therefore, first on an ability to forecast solar changes and, second, on a knowledge of the immediate and subsequent atmospheric effects of such variations."

Improved methods in hygrometry, A. N. Shaw (Proc. and Trans. Roy. Soc. Canada, 3. ser., 10 (1916), Sect. III. pp. 85-92, pl. 1).—This paper describes "experiments with several hygrometers of simple construction which apparently give results of accuracy greater than that given by the instruments in common use." These included a modification of Rideal and Hannah's absorption hygrometer (E. S. R., 34, p. 208), a simple weighing hygrometer, and two electrical methods. The advantages and disadvantages of these methods as compared with the limitations of hygrometric methods in general use are discussed.

Department of meteorology (Nevada Sta. Rpt. 1916, pp. 47-49, flg. 1).—Brief notes are given regarding the work on snow surveying as a means of forecasting water supplies and temperature surveys in the Truckee-Carson Project in western Nevada. It is stated that "a method for the economical and accurate measurement of snow seems now to have been attained in the method of seasonal percentage, which involves the maintenance of a few fixed courses in typical parts of the watershed as a basis for computing the relation of the annual snow cover to normal."

[Meteorological summary] (Idaho Sta. Bul. 92 (1916), pp. 61-63).—Tabular summaries are given of observations on temperature and precipitation at the station at Moscow and the substations at Aberdeen, Gooding, Jerome, and Sandpoint.

New England snowfall, C. F. Brooks (Geogr. Rev., 3 (1917), No. 3, pp. 222-240, figs. 20).—The conditions of temperature, precipitation, and direction of wind, which are the three important factors controlling snowfall, are discussed in some detail. It is stated that as a result of the fact that some of the strongest cyclones pass through the south or southeastern part of New England, "this section from time to time experiences extraordinary snowstorms, a great characteristic of the climate of New England."

Meteorology, C. Flammarion (Ann. Astron.  $\epsilon t$  Mét. [Paris], 53 (1917), pp. 255-288).—Observations at Paris and nearby points on temperature since 1699 and on rainfall since 1689 are summarized, the observations being brought up to 1916.

Climatology of 1915, C. Flammarion (Ann. Astron. et Mét. [Paris], 53 (1917), pp. 387-412, figs. 8).—The conditions of atmospheric pressure, temperature of the air and soil, rainfall, cloudiness, etc., with special reference to the region of Juvisy and the environs of Paris, are summarized. A short note on the relation of cannonading to rainfall is included, the author concluding that observations in connection with the recent military operations in Europe indicate no connection whatever between the two.

The rainfall of Java, B. C. Wallis (Scot. Geogr. Mag., 33 (1917), No. 3, pp. 108-119, figs. 7).—This article reports a study of the distribution of rainfall in Java, with reference to both time and place.

This study showed that "the mountain axis of Java forces the winds to maintain two distinct surface movements, one to the north and the other to the south of the island; the northern coastal lowlands receive, therefore, a different type of rainfall from those of the southern coast. Along the northern coast, out of a total precipitation of about 80 in., during the driest month only about one thirty-second (i. e., 2.5 in.) of the annual fall is precipitated, while during the wettest months at least one-fifth of the precipitation occurs. The ratio of rainfall intensity is thus roughly 1:6. The southern lowlands are relatively wet when the northern lowlands are dry, and vice versa. They receive more rain annually, and the ratio of rainfall intensity is not greater than 1:3.

"The equipluves . . . tend to run parallel to the contours. Consequently, the elevated axis is usually an area of intermediate character with a more intense rainfall on one slope and a less intense rainfall upon the other. This fact is of considerable importance, since it suggests a kind of seesaw arrangement. Most rain is actually precipitated upon the elevated land. When the rainfall tendency comes from the north more water is precipitated on the northern lowlands than on those of the south, but most water falls on the mountain slopes although it does not register so high a pluviometric coefficient. The dry slopes are those which have what may be termed the 'sunny aspect,' i, e., which have the more nearly vertical radiations from the sun. Since the action of the wind is largely frictional, along the slopes rather than up them, neither the west monsoon nor the 'east monsoon' affects the whole island equally. . . .

"The results of this inquiry suggest that in tropical areas wind direction is not a prime cause of rainfall intensity as distinguished from rainfall quantity; but they also suggest that the direction of high mountains serves to restrain the influence of the great factor in producing rainfall intensity. Now these two statements appear to be contradictory, but the cases of Java and Mauritius show that the rainfall cause which is restrained by the mountains is working either in the opposite direction or at right angles to the direction of the prevailing wind."

A short bibliography of literature relating to the subject is given.

### SOILS-FERTILIZERS.

Biological changes in soil during storage, F. E. Allison (Soil Sci., 3 (1917), No. 1, pp. 37-62, figs. 12).—Experiments conducted at Rutgers College to determine how long fresh soil samples may be kept in the laboratory without being appreciably altered in their biological properties are reported. The soils used were shaley loam, gravelly loam, sandy loam, and clay, part being collected in summer and part in winter. In general the work consisted of a study of the bacterial changes from the standpoints of numbers and physiological activity.

It was found that "soils change biologically to a very marked extent during storage in the laboratory, and the rate of change depends largely upon the temperature of the soil when sampled. A change in numbers of bacteria in two hours amounted to as much as 30 to 40 per cent in some soils during the winter months. There is a decided tendency for the ammonification of dried blood and peptone to vary as the numbers of bacteria vary; and for the ammonia production from cottonseed meal to go hand in hand with the numbers of fungi. In the winter there is a diminution in bacterial numbers and usually in ammonification until the end of one week and this is followed by a steady increase. In the summer the decrease in numbers and ammonian production from peptone and dried blood proceeds more slowly and continues for at least two months. To the very end of this experiment the point had not been reached where ammonification ceased to decrease.

"From the data presented . . . It may be said that in order to obtain reliable results during the winter months it is necessary to pour plates for bacterial counts and start all ammonification experiments immediately on bringing the soil sample into the warm laboratory. During the summer months it is desirable to pour plates soon after taking the sample, but this is not as essential as during the colder months. Ammonification experiments need not be started with such haste. During the first ten days the variations in ammonification were almost within the limits of experimental error.

"Air-drying caused a decided decrease in numbers of bacteria except in the case of the Penn loam during the winter months. The decrease was much less

marked for fungi than for bacteria. Air-drying had very little effect on the ammonification of dried blood and cottonseed meal, but caused a pronounced diminution in ammonia production from peptone in solution. Nitrogen-fixation results were very little affected."

Six references to literature bearing on the subject are appended.

A method for determining the volume weight of soils in field condition, C. F. Shaw (Jour. Amer. Soc. Agron., 9 (1917), No. 1, pp. 38-42).—The paraffin immersion method used by Brown et al. in previous work (E. S. R., 25, p. 820) is described.

Soil valuation and soil investigation, T. Remy (Landw. Jahrb., 49 (1916), No. 1, pp. 147-158).—This is a general discussion of important factors in soil investigation and valuation.

The capacity of the soil to absorb and hold water, A. RINDELL (Om Jordens Förmaga att Upptaga och Kvarhålla Vatten. Helsingfors: Kejserliga Senatens Tryckeri, 1915, pp. 34, figs. 8).—This paper deals with the absorptive powers of different soils for water, with special reference to the transportation of nutritive substances in solution by water.

Dynamics of soluble phosphoric acid in the soil (Otchet Bezenchuk, Selsk. Khoz. Opytn. Sta., 5 (1914). pp. 89-100).—Investigations on the solubility of the phosphoric acid in different fallow soils at different times of the year are reported.

The results are taken to indicate that the amount of phosphoric acid extracted from the soil by water, weak acid, or weak alkali does not indicate the amount of soil phosphoric acid soluble in these substances, but rather indicates the dissolving power of the soil solution for soil phosphoric acid. Soil extracts obtained from different parts of the same field showed about the same dissolving powers for soil phosphates. It is concluded that the process of mobilization of phosphoric acid in soil is insignificant. It is thought further that the importance of any particular method of culture as influencing the condition of soil phosphoric acid can not be determined on the basis of present data.

The alkaline reaction produced by acids in soils in relation to plant nutrition.—II, Solubility of manganese compounds in the soil, G. Masoni (Staz. Sper. Agr. Ital., 49 (1916), No. 2, pp. 132-149; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 6, pp. 799, 800; Jour. Soc. Chem. Indus., 35 (1916), No. 23, pp. 1227, 1228; Chem. Abs., 11 (1917), No. 2, p. 181).—Continuing previous work (E. S. R., 34, p. 720), experiments are reported on the action of tenth-normal solutions of hydrochloric, nitric, sulphuric, phosphoric, formic, acetic, oxalic, succinic, malic, tartaric, and citric acids on manganese compounds (1) in common soils, (2) in mixtures of pure calcium carbonate with manganese sulphate, and (3) in a mixture of common soils with manganese sulphate or dioxid. From 25 to 50 gm. of the earth or mixture used were treated with 50 to 100 cc. of the acid solution, the whole was thoroughly shaken, and, after the appearance of an alkaline reaction, the mixture was filtered and the filtrate tested for manganese.

In the experiments with soil it was found that the so-called oxyacids alone threw manganese into solution in large amounts in spite of the alkaline reaction produced. Citric and malic acids were especially active.

In the experiments with pure calcium carbonate and oxids of manganese the ability of lime to prevent the retention of manganese in solution was demonstrated. The oxid of manganese behaved rather differently from the other oxids, giving a comparatively strong manganese reaction in the filtered liquid even with acids other than oxyacids.

With manganese carbonate much smaller quantities of manganese were obtained in solution, even under the action of oxyacids. In the tests with manganese sulphate, quantities of the salt corresponding to 2, 5, and 50 mg. of manganese were used with 15 gm. of calcium carbonate. With the smallest quantity of manganese, whatever the acid used relatively large amounts of manganese passed into solution eight hours from the beginning of acid action. These amounts were largest with citric and malic acids. With 5 and 50 mg. of manganese a strong manganese reaction was found even after 36 and 48 hours.

"Experiments with manganese sulphate and dioxid mixed with earth proved that for small quantities of sulphate (2 mg. of manganese to 50 mg. of earth) the treatment with citric and malic acids alone increased the quantity of manganese passing into solution, while for relatively large quantities (50 mg. of manganese to 50 gm. of earth) the increase in dissolved manganese was marked on treatment with any acid; and that for dioxid there was no increase of the manganese dissolved except on treatment with citric and malic acids."

These results are taken to indicate that compounds of manganese naturally contained in the soil behave in a way similar to that of iron compounds as regards their solubility in acids when lime is in excesss. "The markedly greater capacity of oxyacids for retaining these elements in solution, in spite of the excess of OH occasioned by the acids themselves, is therefore likewise confirmed with regard to the manganese in the soil."

Soil bacteriology, C. M. Hutchinson (Rpt. Agr. Research Inst. and Col. Pusa, 1915-16, pp. 86-89).—Continuing the work of the previous year (E. S. R., 35, p. 626), "a series of field experimental plats under wheat demonstrated the production of infertility in soil containing nitrogenous organic matter (oil cake) as a consequence of semianaerobic conditions artificially induced by waterlogging. This infertility did not occur to the same extent when ammonium sulphate was substituted for cake, nor did the effect of the water-logging become apparent until the roots of the plants had gone down some inches to that level in the soil which oxidation consequent on the cultivation had failed to reach. Parallel plats with barley illustrated this effect more markedly than those with wheat. . . .

"Laboratory work on nitrification and on the growth of seedlings in water and soil cultures demonstrated the possibility of separating substances from certain bacterial cultures, from decomposing organic matter, and from anaerobically incubated soil whose toxicity to nitrifiers, and in greater concentration to seedling plants, was demonstrable under these conditions."

Observations were made on the interference with the growth of seedlings resulting from the bacterial invasion of the unexhausted and still attached seed, and the consequent absorption by the plant of toxic bacterial by-products showed that this invasion occurred most readily in water-logged soil and more especially in the presence of bacteria derived from anaerobically incubated soils of high organic matter content. Copper sulphate was found to neutralize most of the toxic bodies obtained in this way, and seeds treated with this salt were found to be immunized to some extent, although not entirely or invariably, against this action.

It was further found that the presence of nitrites in soils is not alone due to the reduction of nitrates already formed, but that in many of the soils examined in the laboratory nitrites accumulate to some extent before nitrate formation becomes evident, even under conditions apparently favorable to nitrification. The concentration of nitrites required to injure various field crops in soils was found in no case to be so great as that required in water cultures. "Weekly borings and nitrate determinations throughout the year were made in three sets of duplicate plats under grass, . . . wheat and maize, and fallow. . . .

Only in the last of these was there any accumulation of nitrate in the first foot of soil, a much smaller amount occurring in the cropped soil and only very small quantities under grass."

Studies of north Idaho soils, J. J. Putnam (Idaho Sta. Bul. 92 (1916), p. 9).—Ammonification and nitrification studies of two soils, similar to timber soils, showed that "both with ammonium sulphate and blood as the source of nitrogen the presence of 1 per cent of calcium carbonate greatly increases the activity of the nitrifying organisms. The presence of 5 per cent of sawdust greatly lessens the activity of the nitrifying organisms even when calcium carbonate is present. With blood as a source of nitrogen the presence of sawdust greatly lessens the activity of the ammonifying organisms. When 2.5 per cent of sawdust was used, 36.72 per cent of the nitrogen was transformed into ammonia. When the amount of sawdust was increased to 5 per cent, only 27.84 per cent of the nitrogen was transformed to ammonia."

The organic matter of the soil.—III, On the production of humus from manures, R. A. Gortner (Soil Sci., 3 (1917), No. 1, pp. 1-8).—In continuation of work previously noted (E. S. R., 36, p. 815), experiments conducted at the Minnesota Experiment Station are reported on the increase of ammonia-soluble humus brought about by adding powdered silk waste, powdered wool, flour, and alfalfa meal to moist subsoil at respective rates of 500, 460, 50, and 200 gm, per 7,500 gm, of subsoil, and allowing the mixture to undergo natural "humification." Carbon, nitrogen, and humus were determined in the original mixture and in the final product after remaining in a moist condition in the greenhouse for one year.

It was found that there was a decided loss of organic carbon from all of the samples, ranging from a minimum loss of 18.4 per cent to a maximum of 55 per cent of the carbon originally present. There was likewise a loss of nitrogen, but this loss was not proportional to the loss of organic carbon, ranging from 5 to 26.5 per cent of the nitrogen originally present. There was a loss of humus, the material dissolved from the leached soil by 4 per cent NH<sub>4</sub>OH, and this loss appeared to be directly proportional to the loss of nitrogen. In three of the four experiments no significant change was apparent in the materials extracted by 4 per cent NH<sub>4</sub>OH from the unleached soil. In the remaining experiment there was a loss of 60 per cent of the original materials.

"These experiments furnish no evidence that an increase of soil humus is brought about by a specific humification. On the contrary all the evidence is directly opposed to such a conclusion, and it appears altogether probable that the maximum amount of ammonia-soluble material is present in a soil immediately after a green manuring crop has been plowed under and before the humifying bacteria or fungi begin their work."

Eight references to literature bearing on the subject are appended.

The loess soils of the Nebraska portion of the transition region.—VI, The relative "rawness" of the subsoils, F. J. Alway, G. R. McDole, and C. O. Rost (Soil Sci., 3 (1917), No. 1, pp. 9-36, pls. 9, figs. 4).—Pot experiments conducted at the Minnesota Experiment Station with loess surface soils, described in previous reports (E. S. R., 36, p. 421), and with the corresponding subsoils from the second to the sixth foot, using corn, beans, clover, and alfalfa to determine the relative "rawness" or infertility of the subsoils, are reported.

It was found that the soils evidenced no rawness toward the inoculated legumes. "Eight successive crops of alfalfa gave almost as heavy yields on the subsoils from the eastern half of Nebraska as on the corresponding surface soils.

"From field observations on the loess soils of eastern Nebraska it is evident that the deep subsoils at depths of even 20 to 30 ft., both when the surface of these is simply exposed by grading operations and when such excavated material is piled up, are not 'raw' toward inoculated legumes, although very unproductive with nonleguminous crops. In the case of alfalfa they produce practically as satisfactory crops as the adjacent surface soils. After such exposed subsoils have for a period of years been devoted to the production of alfalfa hay it appears that they may be planted to nonleguminous crops with satisfactory returns.

"There is a distinct increase in the nitrogen content of the surface portion of such exposed subsoils, it being much greater when the land is devoted to alfalfa. Even in this case, however, it has by no means attained that of the surrounding surface soils by the time its productivity for nonleguminous crops appears to have been restored. At depths below the plowed area, however, there appears to be no greater gain in nitrogen in the land devoted to alfalfa.

"A field with ordinary surface soil devoted to the production of alfalfa hay for thirteen years showed no distinct enrichment in nitrogen in the subsoil of the second to sixth foot. . . .

"The loess subsoils of the semiarid part, as well as those of the more humid half, of the Nebraska portion of the transition region show, in the matter of rawness, a behavior intermediate between that of arid subsoils and that of the humid subsoils of the eastern and southern United States and of western Europe, with inoculated legumes resembling the former, but with non-leguminous plants, the latter."

Twenty references to literature bearing on the subject are appended.

Soil survey of Latah County, Idaho, J. H. AGEE, G. W. GRAVES, and C. B. MICKELWAITE (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 24, pls. 3, figs. 2, map 1).—This survey, made in cooperation with the Idaho Experiment Station, deals with the soils of an area of 582,400 acres in the west-central part of northern Idaho. "The western and southern parts of the county are rolling prairie, while the extreme eastern and northern parts are mountainous. The south-central part has been dissected by swift-flowing streams. . . Drainage is well established over the whole county."

The soils are of residual, eolian, and alluvial origin. Including rough mountainous land and rough stony land, nine soil types of six series are mapped, of which the Palouse silt loam, Helmer silt loam, and rough mountainous land cover 33.7, 25.7, and 22.5 per cent of the area, respectively.

Soil survey of Wells County, Indiana, W. E. Tharp and W. E. Wiley (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 29, fig. 1, map 1).—This survey, made in cooperation with the Indiana Department of Geology, deals with the soils of an area of 233,600 acres in northeastern Indiana, the topography of which is undulating to rolling. The natural drainage varies with the topography from poor to good. The surface formation throughout the county is a glacial deposit of the late Wisconsin ice invasion.

Including muck and meadow, eight soil types of six series are mapped, of which the Crosby silty clay loam, Clyde silty clay loam, and Miami silty clay loam cover 38.9, 30.2, and 25.7 per cent of the area, respectively.

Soil survey of White County [Indiana], T. M. BUSHNELL and C. P. Erni (Ind. Dept. Geol. and Nat. Resources Ann. Rpt., 40 (1915), pp. 109-155, pl. 1).—This survey has been noted from another source (E. S. R., 36, p. 812).

Soil survey of Van Buren County, Iowa, C. Lounsbury and H. W. Reid (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 32, fig. 1, map 1).—This survey, made in cooperation with the Iowa Experiment Station, deals with the soils of an area of 308,480 acres in southern Iowa, the surface of which consists of a broad, level plain dissected by southeastwardly flowing streams. Fairly good drainage is said to prevail over most of

the county. "There is some deficiency on the broad plateau level in the northeastern part where drainage ways have not yet become thoroughly established."

The soils of the county are of glacial, loessial, and alluvial origin. "The greater part of the county is covered with glacial drift over which lies a thin mantle of loess, and these formations give rise to the upland soils. The alluvial soils include both stream-bottom and terrace or second-bottom types." Fourteen soil types of nine series are mapped, of which the Memphis silt loam and an eroded phase cover 42.4 per cent of the area and the Grundy silt loam 36.7 per cent.

Soil survey of Washington County, Nebraska, L. V. Davis and H. C. Mortlock (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 38, flg. 1, map 1).—This survey, made in cooperation with the Nebraska Soil Survey, deals with the soils of an area of 243,200 acres on the central eastern border of Nebraska. "Physiographically, the county is an old loessial plain, now dissected by dendritic drainage systems. It may be divided into two main topographic divisions, the uplands and the lowlands. Most of the upland consists of undulating to broken land developed by erosion from the old loessial plain. The lowlands consist mainly of first bottoms or alluvial flood plains, but also include flat to undulating terraces or second bottoms. . . . The surface drainage is everywhere good."

The soils are of glacial, loessial, and alluvial origin. Including river wash, 14 soil types of seven series are mapped, of which the Marshall silt loam covers 63.5 per cent of the area.

Soil survey of Davidson County, North Carolina, R. B. Hardison and L. L. Brinkley (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 39, fig. 1, map 1).—This survey, made in cooperation with the North Carolina Department of Agriculture, deals with the soils of an area of 370,560 acres in west-central North Carolina, the topography of which is prevailingly rolling to steeply rolling or badly broken, becoming semimountainous in the southern part. "Many small perennial streams, spring branches, and intermittent streams make up a well-developed drainage system, which reaches all parts of the county. All the first-bottom land along the streams is subject to overflows of short duration."

The soils of the area are of residual and alluvial origin. Twenty-two soil types of 11 series are mapped, of which the Cecil sandy loam, Georgeville silt loam, Alamance silt loam, and Durham sandy loam cover 16.8, 14.4, 9.5, and 8.1 per cent of the area, respectively.

Soil survey of Lewis and Gilmer Counties, West Virginia, W. J. LATIMER (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils. 1915. pp. 34, Ag. 1, map 1).—This survey, made in cooperation with the West Virginia Geological Survey, deals with the soils of an area of 469.120 acres in central West Virginia which lies wholly within the Appalachian Mountain and Plateau Province. The topography in general is steep and broken. Many small streams and spring branches reach well back into the uplands and furnish all sections of the area with good drainage outlets. Owing to the steep topography, the runoff is rapid and drainage is excessive.

The soils of the area are divided naturally into upland or residual soils, terrace, and bottom soils. Including rough stony land, nine soil types of six series are mapped, of which the Dekalb silt loam, Meigs clay loam, and Upshur silty clay loam cover 36.1, 29.7, and 22.6 per cent of the area, respectively.

Arable soils, A. T. CHARRON (Rpt. Min. Agr. Prov. Quebec, 1916, pp. 104-112).—Analyses of 28 samples of arable soils representative of different parts

of Quebec are reported and discussed. Acidity was evident in about three-fourths of the samples.

Stable manure, J. C. Temple (Georgia Sta. Rpt. 1916, p. 11).—Experiments on the influence of stable manure on soil bacteria showed that the increase of bacteria in soils receiving sterilized stable manure and finely cut green oats was greater than in soil receiving unsterilized manure. "The character of the soil's microflora is sometimes greatly changed by the addition of these organic materials. Two soils have been studied in which Actinomyces made up from 79 to 90 per cent of the colonies developing on agar plates. The addition of manure caused a big increase in number of the colonies, but the increase was due entirely to the multiplication of the true bacteria. The bacterial complexes from the soil receiving the unsterilized manure showed much the highest cellulose-dissolving power."

The absorption and washing out of nitrogen from fertilization with nitrates, C. H. VAN HARREVELD-LAKO (Arch. Suikerindus. Nederland. Indie, 24 (1916), No. 7, pp. 207-213; Meded. Proefstat. Java-Suikerindus., 6 (1916), No. 3, pp. 45-51).—This is a review of work by others, the results of which are taken to indicate that nitrates are readily leached out of very pervious soils, and that in tropical soils especially ammonia fertilizers are preferable. See also a previous note by the author (E. S. R., 36, p. 219).

Lime nitrogen as a fertilizer, C. J. Millo (Arch. Suikerindus. Nederland. Indië, 24 (1916), Nos. 19, pp. 709-743, pl. 1, fig. 1; 20, pp. 749-796).—This article deals with the physical and chemical properties of lime nitrogen and reports the general results of experiments on its use as a nitrogenous fertilizer on Java sugar-cane soils. A list of 49 references to literature on the subject is appended.

Residual effect of phosphatic manures on green crops in the year following that of application (Indian Tea Assoc., Sci. Dept. Quart. Jour., No. 3 (1916), pp. 95-102).—Continuing previous experiments (E. S. R., 35, p. 428) on comparative tests of superphosphate, bones, phosphatic slag, and a proprietary basic phosphate with green crops, including sunn hemp, cowpeas, Sesbania aculeata, and Tephrosia candida, it was observed that the different phosphates showed the same order of relative efficiency in the second year as in the first after application, the differences, however, being much less marked. The results obtained with the superphosphate were so much better than with the other phosphates tested that the conclusion is reached that "the use of the less rapidly available forms of phosphoric acid."

Influence of fertilizers and soil amendments on soil acidity, J. J. SKINNER and J. H. Beattie (Jour. Amer. Soc. Agron., 9 (1917), No. 1, pp. 25-35).—" In an experiment growing wheat, rye, clover, timothy, corn, cowpeas, and potatoes, conducted on a heavy silty clay loam at Arlington, Va., calcium sulphate, ferrous sulphate, manganese sulphate, potassium sulphate, and potassium sulphid added singly to the soil annually for five years increased its acidity.

"Magnesium carbonate decreased the acidity of the soil. Soil fertilized with sodium nitrate was less acid than the untreated soil or soil fertilized with acid phosphate or potassium sulphate. Acid phosphate fertilization increased the acidity of the soil, but not as much so as potassium sulphate.

"Organic materials affected the soil differently as to causing acidity. Starch caused increased acidity; stable manure slightly increased acidity, which was still greater with manure leached of its soluble organic and inorganic substances. The leachings from manure produced less acidity than the untreated soil and less than the whole manure or leached manure. The nature of the

decomposition of the organic material in the soil and the character of the life processes in the soil affects the influence of such substances on soil acidity."

The rotary kiln for lime burning—descriptive and comparative, J. G. Jones (Nat. Lime Manfrs. Assoc. Bul. 15 (1914), pp. 16).—The rotary type of kiln for lime burning is described. In a comparison with the vertical kiln it is stated that the rotary kiln has the advantage of better and more uniform burning of the lime.

Soil acidity and the liming of Iowa soils, P. E. Brown (Iowa Sta. Bul. 151, abridged ed. (1915), pp. 22, fig. 1).—An abridged edition (E. S. R., 32, p. 212).

Fertilizer analyses, H. B. McDonnell (Md. Agr. Col. Quart., No. 73 (1916), pp. 30).—This report contains the results of actual and guarantied analyses of 687 samples of fertilizers and fertilizing materials collected for inspection in Maryland from February to June, 1916, inclusive, together with a brief discussion of lime in mixed fertilizers as a drier and filler.

#### AGRICULTURAL BOTANY.

The progressive development of the wheat kernel (Washington Sta. Bul. 136 (1917), pp. 25, 26).—A summarized report is given on studies in which it is stated that inorganic materials are high in the young plant, the largest amount of potassium nitrate occurring in the root and stem just before the formation of the spike, after which time it gradually decreases. Free magnesium falls to a minimum during the formation of the aleurone, while free phosphate rises rapidly to a maximum during the development of the sporogenous tissue, falling to a minimum after the development of the sex cells. Asparagin is considered a very important nutritive substance for growth and it was found together with fructose in all young growing regions. Pectic substances on the stigma are considered especially important in reducing the absorption of water by pollen grains.

From fertilization of the egg to the mature grain, there is a constant translocation of nutrient materials to the growing embryo from the leaves and glumes, these including fructose, glucose, asparagin, arginin, histidin, and leucin. Any excess sugar is at once condensed into starch. Excess asparagin and amino acids remain as such in the endosperm cells until desiccation of the grain begins. Aside from aleurone and protoplasm, in the endosperm just before ripening of the grain are found asparagin, arginin, histidin, and some leucin, but no glutamin. On desiccation of the grain, protein appears in the storage cells and the amino acids and most of the asparagin disappear. The formation of storage protein in wheat is believed to be a condensation process that takes place on dessication of the kernel.

Translocation of seed protein reserves in the growing corn seedling, C. J. V. Pettibone and Cornella Kennedy (Jour. Biol. Chem., 26 (1916), No. 2, pp. 519-525, figs. 2).—The authors describe studies claimed to show that amino acids are present in the flowing sap of corn seedlings. The fact that these compounds are always present in the seed, rootlet, and plumule, coupled with the demonstrated migration of nitrogen, is held to indicate that the transportation of reserve building proteins of the seed occurs in a manner analogous to the transportation of protein food supplies in the animal organism. It is proposed to investigate further certain phenomena suggesting that a portion of the nitrogen may be transported in the form of soluble protein or protein hydrolytic products of the peptid type.

The relation of amid nitrogen to the nitrogen metabolism of the pea plant, B. Sure and W. E. Tottingham (Jour. Biol. Chem., 26 (1916), No. 2, pp. 535-548, figs. 3).—The purpose of this investigation was to determine whether

during germination there is a distinct relation between the disappearance of amino acids and the accumulation of amids, as determined by methods which are described and claimed to be more strictly quantitative than those formerly employed. The investigation consisted in following the changes of the total and water-soluble nitrogen, and the various compounds of the latter, in the etiolated pea plant, which lent itself readily to this purpose and to the methods which are described.

It is stated that in the shoot the percentage of total nitrogen more than doubled in 26 days, but only in cases in which carbohydrate decomposition exceeded protein disintegration. This fact supposedly indicates that during the early stages of growth rapid carbohydrate catabolism occurs in the shoot.

Total nitrogen decreased in the cotyledon, and during early growth a-amino acids accumulated in the cotyledon more than in the shoot. Catabolism is therefore thought to be the predominant type of change in protein material during germination. Water-soluble nitrogen showed a nearly constant proportion to the total nitrogen except in the first stage of growth, when it accumulated considerably. Ammonia, only traces of which occurred in the seed, accumulated during germination. Its fluctuations roughly paralleled those of amid nitrogen, but it decreased in the shoot. Amid nitrogen increased in the shoot throughout all stages of germination, but not so considerably as reported by previous investigators.

Since amids accumulated while carbohydrates and ammonia decreased, it is suggested that the former may have been produced synthetically from the latter compounds. The  $\alpha$ -amino acids accumulated rapidly, especially in the cotyledon, during early growth, but later they decreased in the shoot and disappeared from the cotyledon. The accumulation of amids simultaneously with the decrease of the  $\alpha$ -amino acids and ammonia in the shoot is considered to indicate that  $\alpha$ -amino acids serve for amid production in the nitrogen metabolism of the etiolated pea plant.

The release of oxygen separated during the reduction of nitrates in green plants, M. Molliard (Compt. Rend. Acad. Sci. [Paris], 163 (1916), No. 15, pp. 371-373).—A study of the behavior of radish grown under controlled conditions as regards space and nutritive medium is described. The results appear to indicate that for the fixation of one atom of nitrogen there was a corresponding disengagement of two atoms of oxygen.

Observations on the cytological formation of anthocyanin in living plants, M. MIRANDE (Compt. Rend. Acad. Sci. [Paris], 163 (1916), No. 15, pp. 368-371).—The author has extended to lower plants the studies regarding the mitochondrial origin of anthocyanin, which had been pursued among higher plants by Guilliermond (E. S. R., 35, p. 523), employing for this purpose Azolla fliculoides, which lends itself readily to direct observation in this connection.

He states that he has been able to obtain fresh evidences of the mitochondrial origin of anthocyanin pigment. In case of A. filiculoides, anthocyanin is secreted by granular mitochondria, which in due time emigrating from the central vacuole of the cell become impregnated with a phenol compound which gradually develops anthocyanin pigment. In cases of extreme reddening the anthocyanin is dissolved in the vacuole.

Selective permeability: The absorption of phenol and other solutions by the seeds of Hordeum vulgare, A. J. Brown and F. Tinker (Proc. Roy. Soc. [London], Ser. B, 89 (1916), No. B 617, pp. 373-379, figs. 2).—Previous study (E. S. R., 34, p. 626) on the absorption of aqueous solutions by barley seeds has related mainly to the phenomena attending diffusion of the solvent through the semipermeable seed covering, which is permeable also to certain classes of contained solutes (as phenols and fatty acids), behaving, in fact, rather

as a selectively permeable membrane. The authors have now studied more particularly the entrance of these solutes into the seeds, together with water, in the hope of throwing some light on the physical causes governing selective permeability. A preliminary investigation having shown that phenol and anilin solutions enter the seeds in higher concentrations than the solutions in which they are immersed, quantitative experiments were made employing variously concentrated solutions of anilin, phenol, and acetic acid.

The results are presented in tabular and graphical form with discussion. Pure acetic acid was not absorbed by dry seeds.

The relation between the concentration of various inside solutions and the amount absorbed at equilibrium was also studied, and the results have been tabulated. The various forces involved are discussed.

Some photochemical experiments with pure chlorophyll and their bearing on theories of carbon assimilation, I. Jöbgensen and F. Kidd (Proc. Roy. Soc. [London], Ser. B, 89 (1916), No. B 617, pp. \$42-361, figs. 2).—The authors have examined certain photochemical reactions of chlorophyll observed and hypotheses advanced by previous investigators as a basis for theories of carbon assimilation. Pure chlorophyll was employed in this work as a sol, with water as a dispersion medium, and this sol, in contact with different gases in closed vessels, was exposed to light.

In nitrogen no change occurred in the chromogen complex of the chlorophyll molecule. In carbon dioxid (which here behaved in solution as any other weak acid) phæophytin was produced, but no further change took place in the chromogen complex and formaldehyde was not formed. In oxygen a yellowing, attributed to phæophytin, was observable, and this was followed by a bleaching, the latter development being accelerated and the former omitted when alkali was added. Formaldehyde was produced gradually at first, but more rapidly after bleaching was completed, increasing to a maximum and then diminishing, while acidity increased throughout. It is suggested that formaldehyde arises mainly from the phytol, which is presumably split off from the chlorophyll molecule under light and oxygen.

Aeriferous tissue in willow galls, A. Cosens and T. A. Sinclair (Bot. Gaz., 62 (1916), No. 3, pp 210-225, pls. 3, figs. 5).—The failure of all attempts by varying environment to develop or increase the aeriferous tissue where found in certain portions of insect galls is considered to prove that they are heritable tissues. The reinstatement in a gall of vestigial characters of the plant is considered to have an important bearing on the question of gall formation. It is claimed that there is no authentic instance of any organ or tissue in a gall that is new, ontogenetically or phylogentically, to the host in question.

Improvements in the method for determining the transpiring power of plant surfaces by hygrometric paper, B. E. Livingston and Edith B. Shreve (Plant World, 19 (1916), No. 10, pp. 287-309).—The authors have given in considerable detail the results of several years of work on improvements which are claimed to render field tests of the transpiring power of plants much less arduous and more precise than was formerly the case. These improvements relate to the elimination of repeated field tests over the standard evaporating surface, the substitution therefor of a thermometer reading and a simple arithmetical calculation, the introduction of composite paper slips including two permanent color standards and the use of small desiccators for keeping the slips dry and at air temperature until a test is to be made, improvements in the standard evaporating surface, and a more uniform cobalt chlorid paper than any previously employed.

Germinability tests with seeds of Lepidium sativum under diverse conditions, P. Lesage (Compt. Rend. Acad. Sci. [Paris], 163 (1916), No. 18, pp. 486-

489).—Employing the potash test previously mentioned (E. S. R., 25, p. 222) for determining germinability or its absence, the author has experimented with seeds of pepper cress in alcoholic or in saline solutions, in petroleum ether or in ordinary ether, in moist air and in oxygenated water. He has detailed the results of the several tests, with some references to observations previously made by himself (E. S. R., 27, p. 330) and by Demoussy (E. S. R., 36, p. 29).

Influence of the medium upon the orientation of secondary terrestrial roots, R. M. Holman (Amer. Jour. Bot., 3 (1916), No. 8, pp. 407-414, figs. 3).— The results arrived at by the study, previously noted (E. S. R., 35, p. 223; 36, p. 129), of the primary roots of Vicia faba, Lupinus albus, and Pisum sativum suggested the question as to whether or not the secondary roots of these species show any relation between geotropic behavior and medium, such as exists in primary roots. The author has carried out a series of experiments, chiefly with V. faba, in the course of which a striking parallel was noted between the behavior of primary roots and secondary roots of the first order, the media used being air as nearly as possible saturated with water, uniformly moist sawdust, and fine garden earth. The results are described in detail.

The growth of forest tree roots, W. B. McDougall (Amer. Jour. Bot., 3 (1916), No. 7, pp. 384-392).—A series of systematic observations, by means of two methods described, on growing roots of Quercus alba, Tilia americana, Carya laciniosa, and Acer saccharinum, are considered to show that the root growth of forest trees corresponds to the warm period during which absorption can go on. Any possible resting period in summer is deemed due to scarcity of water and not to any inherent tendency of the plants toward periodicity in growth.

The toxicity of bog water, G. M. Rigg (Amer. Jour. Bot., 3 (1916), No. 8, pp. 436, 437).—A brief statement is given regarding data obtained from studies on waters taken from sphagnum bogs of the Puget Sound region and Alaska, in relation to the injurious effect of such waters on certain plants (in this case Tradescantia cuttings). The author considers these data to warrant the suggestion that its content of colloidal matters is a large factor in the toxicity of this water to certain plants.

Experimental cultures of plants on the seashore, L. Daniel (Compt. Rend. Acad. Sci. [Paris], 163 (1916), No. 18, pp. 483-486).—During fifteen years of experiments with various plants which had been taken from Rennes to Erquy and there grown under exposure to spray and intermittent wetting with sea water, no change of real significance or permanence occurred, so far as could be detected. Any differences due to abundant or deficient water supply showed a tendency to disappear quickly when the plants were returned to their former environment.

The establishment of varieties in Coleus by the selection of somatic variations, A. B. Stout (Carnegie Inst. Washington Pub. 218 (1915), pp. 80, pls. 4, flgs. 4).—The author reports that a single variety of Coleus propagated vegetatively by cuttings in two main clones has shown gradual fluctuations and sudden mutations, giving a total of 16 distinct and characteristically different color patterns. The results indicate that slight variations, arising either as sudden mutations or as gradual fluctuations, can perpetuate themselves. It is claimed that bud variations in Coleus are common, give numerous different types which may be vegetatively constant from the first or can be made so by selection, show development of certain types more commonly than others, produce reversions to parental types, give development of different degrees of variability among sister clones, and exhibit spontaneous changes in the fundamental color characters and in the cellular and tissue processes resulting in color patterns. The results of the investigation indicate that in Coleus asexual

and sexual reproduction are not fundamentally different in respect to the extent and range of variation.

A bibliography of literature pertaining to the subject is given.

Mutation in Matthiola annua, a "Mendelizing" species, H. B. Frost (Amer. Jour. Bot., 3 (1916), No. 7, pp. 377-383, figs. 3).—The author states that six or seven of the series of types noted previously (E. S. R., 28, p. 439) as having sprung from M. annua have reproduced themselves in progeny tests, some through several generations, though only the early (few-noded) type has proved to be evidently homozygous. A brief characterization is given of eight of the mutant types, including all that have proved to be hereditary.

The mutant individuals are considered to be not extracted pure recessives but heterozygous dominants, and (since they have occurred many times in cultures from selfed parents) not due to combination of complementary factors by cross-fertilization. They are considered to be due to definite changes in the germ plasm distinct from the shiftings which result from ordinary Mendelian phenomena.

Correlations between morphological characters and the saccharin content of sugar beets, F. J. Pritchard (Amer. Jour. Bot., 3 (1916), No. 7, pp. 361-576, figs. 8).—Extensive statistical data obtained from a study of beets are said to show correlation coefficients between root weight and sugar percentage of -0.253, -0.258, -0.254, -0.257, and -0.499; between weight of root and quantity of sugar, 0.920. Correlation between percentage and quantity of sugar in roots of 35 gm. range in weight was nearly perfect, being 0.93, 0.96, and 0.99, but no such correlation appeared in roots of miscellaneous sizes. Correlation was slight or absent between other qualities noted.

Anomalies in Beta vulgaris, O. Munerati and T. V. Zapparoli (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 25 (1916), I, No. 12, pp. 816-822, figs. 6).—This is a progress report on the continuation of studies previously noted (E. S. R., 35, p. 436). Morphological deviations, which have proved to be much more frequent than formerly appeared, are reported on as regards the portions of the plant involved, and certain correlations have been observed.

Green manures and manuring in the Tropics, including an account of the economic value of Leguminosæ as sources of foodstuffs, vegetable oils, etc., P. DE SORNAY, trans. by F. W. Flattely (London: John Bale, Sons & Danielsson, Ltd., 1916, pp. XVI+466, figs. 74).—In this translation from Les Plantes Tropicales Alimentaires et Industrielles de la Famille des Légumineuses, the author, after summarizing investigations and theories regarding the fixation of free atmospheric nitrogen by leguminous plants, describes about 40 species that are more or less extensively grown in the Tropics as green manure crops, as well as for forage and other purposes. Comparisons are drawn between several common species as to their relative values in rotation experiments. Chapters are devoted to the presence of manganese and prussic acid in leguminous plants, a description of the principal starches they contain, their uses in agriculture and various arts, insect and fungus pests, etc. Much of the information is derived from reports of experiments conducted in various countries, but the author adds much original matter from his own investigations at the agricultural station of the island of Mauritius.

#### FIELD CROPS.

[Report of field crop work at the Georgia Experiment Station], C. K. Mc-CLELLAND (Georgia Sta. Rpt. 1916, pp. 7-9, 28-31).—Fertilizer tests with corn showed an increase of 13.4 per cent when fertilizer was applied around the corn

instead of under it. In testing the amount of fertilizer to apply to corn, 1,000-lb. applications resulted in the highest yield, 27.9 bu. per acre, as compared with 18.9 bu. on the check plat and from 20.5 to 25.5 bu. from 200- to 1,200-lb. applications. A yield of only slightly more than 8 bu. per acre of corn was realized from a field in which velvet beans were sown with the corn. In a comparison of basic slag with acid phosphate the yield with the latter was 23.2 bu., with the former 22.5 bu., and the check 20 bu. per acre.

Fertilizer experiments with cotton showed a gradual increase in the yields of seed cotton with increasing amounts of fertilizers, the increase over the check varying from about 22 per cent with a 200-lb. to 50 per cent with a 1,200-lb. application. There was no material difference in yields of cotton when fertilized with either basic slag or acid phosphate. A comparison of early with late thinning of cotton gave increased yields in favor of the latter method of 26 lbs. of seed cotton per acre for the Trice variety and 28 lbs. for the Sunbeam variety.

Top-dressing small grains with nitrate of soda gave slightly better results than the use of sulphate of ammonia, both being superior to cottonseed meal. The latter, however, doubled the yield of oats. In preparing for oats after peas double disking was followed by a yield of 44 bu., deep plowing by one of 53 bu., and shallow plowing by one of 55 bu. per acre.

Brief notes are given on Sudan, para, teff, Giant Bermuda, rescue, redtop, and Kikuyu grasses. Rescue grass is reported as the best winter grass.

In experiments with leguminous plants, seeding tests with alfalfa showed no difference in stand by different times or depths of plowing, manured or unmanured, with lime plowed under or left on top of plowed land, or with different rates of seeding. There was a difference with different amounts of limestone applied per acre, 1 ton proving insufficient to overcome the soil acidity while slight difference was realized between 2- and 3-ton applications. Analyses of roots and stubble of crimson clover showed a nitrogen residue of 46 lbs. per acre.

Studies of the water requirement of cotton have been continued. An apparent regularity in the blooming of the cotton plant has been observed in that the time between horizontal blooms was double that between vertical blooms, a given bloom opening on the same day as the one on the second branch above but one node nearer the central stalk of the plant. The period of greatest moisture requirement was found to be from the middle of July to late August.

Observations on the germination of cotton seed sown after turning under a green manure crop are reported for purposes of comparing field conditions with those observed by Fred (E. S. R., 35, p. 24) under greenhouse conditions. It was concluded that there is some injury to germination (from 0.7 to 5.1 per cent) from the use of a green manure crop, but that the difference in field plantings is not sufficient to militate against the use of such a crop. The observations indirectly showed a benefit from the early planting of the green manure crop in the fall to afford sufficient growth to make early spring plowing permissible.

[Report of field crop work], G. S. RAY, C. M. EKLOF, P. P. PETERSON, and G. W. Graves (*Idaho Sta. Bul. 92 (1916*), pp. 19-22, 30-34, figs. 4).—This reports the continuation of field crop work previously noted (E. S. R., 34, p. 734).

Variety tests are noted with winter and spring varieties of wheat, oats, barley, rye, field peas, and corn. The leading varieties and their respective yields were as follows: Red Russian winter wheat 59.7, Jenkins Club spring wheat 72, Tennessee Winter barley 47.9, with the 4-year average for

white winter barley 67.1; Hannchen spring barley; Colorado 37 spring oats 168.7 (all winter oats winterkilled); Invincible winter rye 58.9; and Amraoti field peas 53.3 bu. per acre. Minnesota 13 was the only corn variety to mature seed. Idaho White Dent produced 15.8 tons of silage per acre when cut in the glazed stage. The best silage production from Rustler White Dent with different planting methods was 16.1 tons, secured from rows 30 in. apart and hills 3 ft. 8 in. apart.

A seeding of 90 lbs. of field peas and 32 lbs. of oats gave the highest yield of hay, 4.6 tons, in a comparison of different rates of seeding. In cultural tests with field peas the highest yield, 70.5 bu. per acre, was secured from broadcasted seed plowed under.

In crop rotation experiments on Palouse silt loam a yield of 76.1 bu. of wheat was secured after potatoes as compared with a yield of 25.3 bu. after oats, 29.8 bu. after wheat, 48.4 bu. after corn, 51.2 bu. after peas, and 63.1 bu. after fallow. Fertilizer experiments on this soil showed an apparent average increase in yield of oats due to fertilizers added in 1915 of 19.8 bu. for nitrogen, 2.5 bu. for potash, and a 2.4-bu. loss for phosphorus. Similar tests with wheat were deemed inconclusive because of smut.

[Report of field crop work at the Aberdeen substation], L. C. AICHER (Idaho Sta. Bul. 92 (1916), pp. 36-42, figs. 3).—This reports a continuation of work previously noted (E. S. R., 34, p. 734), including cultural tests with clovers, sugar beets (seed), peas, alfalfa, wheat, and potatoes, and variety tests with wheat, oats, barley, potatoes, and field peas, etc.

In the potato culture work a yield of 520 bu, per acre was obtained from a plat planted with the stem ends only of 3-oz, seed cut in half.

[Report of field crop work] (Iowa Sta. Rpt. 1916, pp. 22, 23, 29).—Cooperative trials with Iowa 103 and Iowa 105 oats, originated at the station, show an approximate increase of 5 bu, per acre over common varieties. The winter wheat variety has exhibited great hardiness under conditions that resulted in severe winterkilling with most commercial varieties. This variety has also been grown in Minnesota and North and South Dakota, the winterkilling in these regions being reported as about 5 per cent.

The Ames scarifying machine is reported as having increased the germinability of various clover seed, especially sweet clover, to over 90 per cent, when in many cases previous to treatment germination was not over 20 per cent.

In pollination studies with clover and alfalfa, conducted in cooperation with the U. S. Department of Agriculture, it was found that moisture conditions were a determining factor in the setting of red clover seed, as little fertilization occured when the flowers were wet. In July the interval between pollination and fertilization was about 18 hours, and in October from 35 to 50 hours. The bumblebee is found an efficient pollinator of red clover, while the honeybee is occasionally so. The clover cross-pollinating machine and hand-pollinating brushes were not satisfactory.

J. N. Martin found that the setting of the seed pods in alfalfa is dependent upon the proper functioning of the pollen and that germination of the pollen is dependent upon the moisture supply. If the supply of soil and atmospheric moisture is above or below the optimum, germination is inhibited. Blasting of the seed is due to the arrested development of the embryo caused either by pathological conditions or the inability of the plant to furnish the required moisture.

Irrigation experiments with alfalfa, sugar beets, potatoes, and wheat (Nevada Sta. Rpt. 1216, pp. 30-34).—Experiments similar to those previously noted (E. S. R., 36, p. 35) were continued during the season of 1915.

Alfalfa was given 6-, 9-, and 12-in. applications of water before and at the time the plants showed need of water by the dark green color of the foliage and when the plants had suffered for water as indicated by the dark green color of the foliage and drooping leaves. The results show that alfalfa can not be allowed to reach the wilting stage without materially descreasing the yield of hay. Where the plants were never allowed to show need of water the yield was higher with a 6-in. than with a 9-in. application, but slightly lower than with the 12-in. application. The greatest total yield was had at the expense of yield per acre-foot of water and of quality of hay, the latter being due to the large proportion of coarse stems to leaves. A gradual decrease in yield was noted with the same applications of water applied as the wilting stage advances. Alfalfa responded better than wheat, potatoes, and sugar beets to heavy applications of water, but not so well as did clover the previous year.

Potato yields were seriously affected by dry rot, but comparative results for 1914 and 1915 indicate that light applications of water are preferable under all conditions. Very little difference in yield is shown, however, where the crop receives four, six, or eight 3-in. applications. Where the plants wilted before irrigation a second growth was made, resulting in lowered starch content. Plats receiving over 24 in. of water produced very scabby potatoes.

The average results with sugar beets for 1914 and 1915 indicate that plants irrigated after having wilted and failed to revive at night will not produce a profitable crop. Only slight variations in yield were realized from 2-, 4-, and 6-in. applications, or from total applications of 12-, 18-, and 24-in., this being partly attributed to the lateral diffusion of moisture from one plat to another. The sugar content was not materially affected by the stage of wilting or depth of application. The purity of the juice varied with the stage of wilting, being greatest in beets which received 6-in. applications after the plants wilted down and failed to revive at night. The beets in this plat produced 5.36 tons per acre, while the highest-yielding plat produced 11.8 tons.

The wheat experiments were altered in that 3-, 5-, and 7-in. applications were made instead of 3-, 4.5-, and 6-in. applications, as previously, the stages of growth remaining the same. The plats were harvested from August 9 to 17, those receiving the least total irrigation, when an irrigation at the milk stage was omitted, attaining maturity first. The three highest yields were obtained from plats receiving four 7-in, applications, that on which the irrigation at the 5-leaf stage was omitted, being first with 34.7 bu. per acre, with that on which the irrigation at the boot stage was omitted second, and that on which the irrigation at the dough stage was omitted third. With the omission of irrigations at the 5-leaf and dough and the milk and dough stages, the yields were 28.5 and 27.8 bu, per acre, respectively, and a marked decrease in yield was noted on all other plats where two irrigations were omitted. With a 7-in. application at each stage of growth a yield of 24.2 bu, per acre was obtained. The yield obtained with four 7-in, applications when the irrigation at the milk stage was omitted was 27 per cent less than the highest yield, 11 per cent less than when the irrigation at the boot stage was omitted, 6 per cent less than when the irrigation at the dough stage was omitted, and 8 per cent more than when the irrigation at the bloom stage was omitted, thus indicating that the bloom and milk stages are critical periods in the irrigation of the wheat crop.

With only two irrigations the yields were lower in all cases, but the 6-in. application before heading and the 12-in. application after heading produced the greatest yield, 27 bu. per acre. Nine- and 12-in. irrigations before heading provided an excess of water over that utilized by the crop, as shown by decreased yields amounting to 39 and 40 per cent, respectively.

In a comparison of 3- and 7-in. applications, 83 per cent of the results were strongly in favor of the 7-in. applications, with an average increase in yields of 28.7 per cent and a maximum increase of 87.6 per cent where one irrigation at the boot stage was omitted. Where irrigations were omitted at the 5-leaf and bloom stages, boot and bloom stages, boot and milk stages, and bloom and milk stages, the 3-in. applications are about as effective as twice that amount in supplying the water requirements of the crop, but the omission of these applications greatly decreased the yield, 19.9 bu. being the highest production in any of the last four instances.

The minimum soil moisture content for the first 2 ft. was 11.6 per cent before the irrigation at the milk stage and where two irrigations were omitted at the boot and bloom stages, and the maximum 16.5 per cent where irrigations at the 5-leaf and dough stages were omitted. Only 1.5 per cent maximum average difference down to 6 ft. was realized between 3- and 7-in. applications where two irrigations were omitted. When one irrigation was omitted the variation in moisture content between 3- and 7-in. applications was greater. The 7-in. applications at the first foot showed an increase of 14.8 per cent over that of the 3-in. applications, a 10 per cent increase for the second foot, a 12 per cent increase for the third foot, and a 3 per cent loss for the fourth foot.

Variety testing and crop improvement (Nevada Sta. Rpt. 1916, pp. 34-37, fgs. 2).—Variety and selection tests are reported with wheat, oats, barley, corn and sorghum (for silage), field peas and beans, millets, potatoes, and field beets.

[Report of field crop work] (New Mexico Sta. Rpt., 1916, pp. 34-49, flgs. 3).—Potato experiments for 1916 included plantings receiving stable manure, level and ridge cultivation, cultivation by the Greeley system, 10- and 3-in, winner irrigations, no winter irrigation, no summer irrigation, no winter or summer irrigation, and 1, 2, and 3 summer irrigations. The rainfall amounted to 1.89 in. The highest plat yield was secured where the Greeley system of cultivation had been practiced and where 3 summer irrigations but no winter irrigation had occurred. The second highest yield was obtained from a plat receiving the level cultivation, 2 summer irrigations, and 1 10-in, winter irrigation. Both plats were manured.

Of 11 varieties of sorghum tested for silage, sumac sorghum gave the highest yield, 14.3 tons of green forage per acre, and White Durra the lowest, with 3.2 tons per acre.

In cultural and variety tests with corn, Mexican June sown with a planter and with irrigation preceding planting gave the highest yield, 52.4 bu. per acre. The lowest yield, 11.7 bu., was secured with Hickory King under the same conditions.

Sudan grass seeded in rows gave a total yield of 7,428 lbs. as compared with 6,261 lbs. on a plat seeded broadcast, and required an average of 284 lbs. less water in the production of dry matter.

Sugar beet tests included a study of spring and fall planting dates, involving a comparison of spring and fall planting, a comparison of the furrow method of irrigation with the flooding method, and a comparison of irrigating before and after planting. Beets planted in January were ready to harvest in July and tested 14 per cent sugar with about 85 per cent purity.

A study is being made of the duty of water, with special reference to alfalfa production. In the season of 1915-16 five cuttings of alfalfa were secured, averaging 6 tons per acre with an average duty of water of 40 acre-inches.

Farm crops (Washington Sta. Bul. 136 (1917), pp. 10-19, 29, 30, fg. 1).— This reports the work of the 1915 season and the plantings for 1916. In inheritance studies the F<sub>2</sub> generation of hybrid seed from true spring varieties of barley when seeded in the spring produced 18.75 per cent of winter plants and 81.75 per cent of spring plants.

The following varieties yielded best for their respective crops for two years: Winter wheat, Triplet, 49.37 bu.; spring wheat, Chul × Bluestem, 32.79 bu.; oats, Abundance; winter barley, Tapp, 64.1 bu.; spring barley, Blue Barley, 64.77 bu.; and field peas, Canada, 28.5 bu. (one year).

Variety tests at Ritzville under a 12-in, rainfall and summer fallowed ground were continued in 1915. Hybrid 143 gave the highest yield of winter whent varieties, 54.4 bu.; Early Baart, of spring wheat varieties, 52.6 bu.; Blue Barley, of the barleys, 82.5 bu.; and Sixty Day, of the oats, 76.25 bu.

Environmental tests conducted in cooperation with the U. S. Department of Agriculture were continued.

Rotation and cultural experiments extending over a period of 15 years indicate that the plat growing corn and winter wheat in alternate years has given the greatest total yield of grain for 15 years and ranked among the highest in yield of winter wheat in 1915 (45 bu. per acre). The plat giving the highest wheat yield in 1915 (46 bu. per acre) was on a 5-year rotation of clover and timothy, 1911 and 1912; oats and peas (10 tons of manure per acre), 1913; corn, 1914; and wheat, 1915. The plats in rotation gave larger yields in general than those growing wheat continuously, either annually or in alternation with summer fallow.

Approximately 2,000 nitrogen determinations were made of different varieties of wheat grown under different conditions. The spring wheats grown at Pullman were high in nitrogen content, the lowest percentage, 2.41, being found in Red Chaff and the highest, 3.15, in Little Club. Among the winter wheats Jones Winter Fife was lowest, with 2.11 per cent, and Turkey × Bluestem Hybrid highest, with 3.03 per cent. The highest average nitrogen content, 2.82 per cent, occurred in wheat grown on summer fallow, while the lowest, 1.62 per cent, occurred in wheat grown on ground used for the production of wheat hay the previous year. Following summer fallow the nitrogen content diminshed in order after the following crops: Potatoes, carrots, beets, beans, and peas.

Alfalfa fertilizers, G. G. Brown (Oregon Sta. Bul. 141 (1917), pp. 55, 56).— Field experiments at Hood River to determine the relative influence of land plaster (gypsum) and flowers of sulphur on alfalfa are briefly reported.

A 100-lb. application of land plaster to unthrifty plants was followed by a total yield of 7,522 lbs. of cured hay per acre, as compared with a yield of 2,104 lbs. on the untreated plat. Doubling the treatment resulted in a total yield of only 5,660 lbs. In this experiment an application of air-slaked lime, followed by a 100-lb. application of land plaster after the first cutting, resulted in greatly increased vigor and a total yield considerably in excess of the untreated plat.

An application of 16.6 lbs. of sulphur (the sulphur equivalent of 100 lbs. of land plaster) was followed by a total yield of 7,650 lbs. of cured hay per acre, or 890 lbs. in excess of that for the check plat. With a 200-lb. application of sulphur 9,880 lbs. of hay was produced. Land plaster applied at the rate of 100 lbs. per acre in this series showed a total yield of 11,300 lbs. of hay per acre. A gain of 400 lbs. of hay per acre per cutting was obtained following a 200-lb. application of land plaster, 100 lbs. applied in March and 100 lbs. applied after the first cutting.

Another series of experiments on which data for the first two cuttings only were secured showed a total yield of 6,500 lbs. per acre following a 200-lb.

application of sulphur and 8,300 lbs. following a 100-lb. application of land plaster.

Air-slaked lime and nitrate of soda were also tested, but failed to give increased yields.

It is recommended that sulphur be applied not later than January or February, while land plaster should be applied early in March.

Studies by means of both pot and solution culture of the phosphorus and potassium requirements of the barley plant during its different periods of growth, F. R. Pember (Rhode Island Sta. Bul. 169 (1917), pp. 50, pls. 2, flgs. 3).—Investigations are reported to determine the actual requirements of the barley plant for potassium and phosphorus during different periods of growth and where most of the conditions essential to growth were under control. The experiments include (1) those with plants grown in sand or soil and (2) those with barley grown in solutions.

The first group of experiments included four tests of varying applications of potassium and phosphorus applied at different periods in the growth of barley grown in sand, a study of the relation of vigor of growth of the young plants to the percentage of phosphorus contained in the seed, and a comparative study of oats grown in sunken pots out of doors.

Tests for the potassium requirement of the barley plant grown in sand were not continued after the first experiment because of the large growth the plants were capable of making when no potassium was added. Where little or no potassium was added, the plants showed spots or flecks of brown on the oldest leaves, the discoloration being greatest when no potassium was added. Plants grown without the addition of phosphorus were darker green and showed considerable purple in their stalks and leaves.

In the sand experiments the weight of dry straw, or straw and roots, was practically the same whether all of the phosphorus was added at the beginning in three equal applications, or one-third at the beginning and one-third at the end of the second period, or two-thirds at the beginning and one-third at the end of the second period. In the third experiment the amount of seed produced was much greater where phosphorus had been received in three equal applications, while in the fourth experiment plants having the full phosphorus application at the beginning produced the most seed.

Selected barley seed varied in the percentage of phosphorus contained, but the weight of the entire dry plants grown from similar seeds bore no relation to the amount contained. Plants grown for 19 days from planting with a full phosphorus application at their disposal were not markedly larger than those having only a one-third application of phosphorus, but the amount of phosphorus recovered from the former was more than twice that recovered from the latter. In the fourth experiment, the amount of phosphorus recovered from the plants harvested at the end of the second period was much the same whether the full phosphorus application was made at the beginning, or one-third at the beginning of both the first and second periods. The best recovery of phosphorus by the barley plants grown in sand was about 89 per cent of the amount added.

Out plants grown in 1909 in soil receiving the full phosphorus application before planting were larger and recovered more phosphorus than those which had three equal applications, but the latter produced a larger amount of seed. In the season of 1910 these differences were negligible. The best recovery of phosphorus by the out plant was one-fifteenth of the amount added.

The second group of experiments dealt with the actual requirements of the barley plant for potassium and phosphorus during its different periods of growth in solutions. Studies were made of the phosphorus absorption during

fortnightly periods; the effect of different cultural methods, of boron and manganese, and of varying the relation of the potassium, nitrogen, and phosphorus; applications of potassium and phosphorus made according to certain curves; the stage of growth at which the minimum phosphorus is best utilized; the ability of barley plants to utilize phosphorus if it is mainly withheld until the last four weeks of growth; and the necessary amount of phosphorus for the optimum growth of the barley plant. The results of these investigations are briefly summarized as follows:

Ten plants receiving an average of 13 mg. of  $P_2O_5$  per week for the first 10 weeks absorbed nearly all of it, while plants receiving the maximum amount of phosphorus absorbed about 30 mg.  $P_2O_5$  per week from the third to the sixth week, inclusive. The small application of phosphorus was sufficient for the needs of the plants but the percentage of phosphorus recovered was much increased by the largest application. Plants receiving minimum amounts of phosphorus the first eight weeks of growth were noticeably handicapped in size and in color of stems and leaves, while those receiving liberal amounts of phosphorus during the next four weeks made a liberal growth and appeared perfectly normal at harvest. The minimum phosphorus requirement for 10 plants producing the optimum amount of seed was about 75 mg. of  $P_2O_6$ .

Plants grown in cultures and receiving 80 mg. of  $K_2O_5$  did not mature seed, were limp, and showed a marked spotting of stems and leaves. The amount of potassium recovered from the seed showed little variation regardless of the amount of potassium applied, while the amount recovered from the seed-free plants was markedly influenced by the amount added.

The amount of potassium, nitrogen, or phosphorus absorbed by the plants was greatly influenced by the relation of the other nutrients. Changes in cultural methods, that is, aerating the solutions daily, keeping a piece of fresh charcoal in the solutions, or lowering the temperature of the solutions in summer weather, had no noticeable influence on plant growth. Titrations of certain composite samples of the residual solutions showed slight variations from the neutral point. In the quantity used in these tests, the addition of boron or manganese to the culture medium had no apparent effect upon the growth of the plants.

Results of tests made for potassium and phosphorus in distilled water, in which plants were allowed to remain for one to two weeks after they attained their growth, did not substantiate the belief that either element was freely given off by way of the roots at maturity.

Report on corn and cotton varieties, 1916, C. K. McClelland (Georgia Sta. Circ. 75 (1917), pp. 8).—This reports the results of variety tests with corn and cotton for 1916 and is a continuation of work previously noted (E. S. R., 35, p. 830).

Fifteen varieties of corn were tested. Scott Marlboro and Steinheimer Marlboro gave the highest yields of 22 and 21 bu., respectively, while Rockdale gave the lowest yield of 12.6 bu. per acre. Nearly all of the varieties were the prolific two-eared type.

Of 28 cotton varieties tested, Wanamaker Big Boll, with a yield of 1,575 lbs., and Smith Piedmont Big Boll, with a yield of 1,550 lbs. of seed cotton per acre, were the leading varieties. Forty-nine per cent of the bolls of the former and 60 per cent of those of the latter were open by the second picking, October 6. Blackshear Wilt-Resistant Lee, with a yield of 960 lbs., was the lowest yielding variety. The Cleveland types of cotton, which have led in variety tests 8 out of the last 11 years, are considered the best all-around varieties for the middle Piedmont region. These varieties yielded from 1,310 to 1,420 lbs. of seed cotton per acre this past year.

The Cleveland, Sunbeam, Triumph, Cook, and other similar types are recommended for use as weevil-resistant varieties, due to their high yielding qualities and in the event that early maturity can be developed. Covington-Toole, Tri-Cook, Dix-afifi, and Lewis No. 63 are recommended for sandy soils as being early enough for weevil and wilt resistant.

Farm practice in the cultivation of cotton, H. R. Cates (U. S. Dept. Agr. Bul. 511 (1917), pp. 62, figs. 20).—Extensive studies of cultural practices with cotton are reported, giving tabulated data secu: 1 from a survey of 25 or more farms in each of 19 representative areas of the cotton belt. Complete farm records were secured, showing in detail the tillage practices and farm conditions. The data are summarized and discussed, but no attempt made "to recommend any certain methods for cultivating cotton."

In summarizing these studies the author indicates that the yields of cotton are governed largely by climatic conditions, the inherent fertility of the soil, the quantity of commercial fertilizers used, and the character of the tillage given. Cotton yields are directly related to the amount of tillage given after planting. Furthermore, the kind of tillage given and the implements used are determined largely by economic conditions, topography, soil type, and custom. The amount of tillage depends chiefly upon the kind and number of weeds, economic conditions, and the prevailing weather.

A study of cotton market conditions in North Carolina with a view to their improvement, O. J. McConnell and W. R. Camp (U. S. Dept. Agr. Bul. 476 (1917), pp. 18. fig. 1).—Investigations are described made for the purpose of ascertaining the value to the cotton producer of a knowledge of the class of his cotton before sale and to determine whether this information could be furnished to producers by disinterested parties with practical results. A detailed study of local conditions affecting cotton marketing was made in the eastern part of North Carolina during the season of 1914-15 and embracing all cotton-producing sections of the State during 1915-16.

Data are presented showing the character of the cotton produced, the relative merits of certain primary markets in North Carolina, and a comparison of prices received for classed cotton with those received for unclassed cotton.

The cotton samples graded and stapled during the period of this study showed an average grade of slightly above Middling. The use of more modern gins, especially in the Coastal Plain section, would raise the average grade in the State.

Marketing conditions on the whole were better in the Piedmont than in the Coastal Plain section, the grading and stapling of individual bales being given more consideration.

Account sales were at a higher rate than cash sales on coinciding dates and the range in prices for credit sales greater than for cash sales. As a rule, however, the gain is compensated by the higher price charged for the goods represented by the account.

It is estimated that the average producer who knew the class of his cotton profited about \$1.15 per bale, and it is suggested that counties producing 5,000 or more bales would profit by employing a county classer as provided for by the State grading-law.

The relative value of different grades and lengths of staple was more nearly approximated in the sale of classed cotton than in the sale of unclassed cotton. This should stimulate the producer to exercise more careful selection of varieties and more care in handling the product. Producers selling in lots of 10 or more bales received 88 cts. to \$1.45 per bale more than those selling one or two bales, indicating the economic value of pooling or selling organizations.

Handling and marketing Durango cotton in the Imperial Valley, J. G. Martin and G. C. White (U. S. Dept. Agr. Bul. 458 (1917), pp. 22, figs. 6).— This reports studies of the marking, tagging, and sampling of the bales, concentrating the cotton into small lots of a few bales each, and into minimum carload lots for compression, undertaken by the Office of Markets and Rural Organization in cooperation with the Imperial Valley Long-Staple Cotton Growers' Association to assist the growers of Durango long-staple cotton in the Imperial Valley in the handling, classing, and marketing of their product. The studies also afforded an opportunity for studying the field conditions under which Durango cotton is produced and to inspect the methods of picking, handling, and storing of the seed cotton on the farm, the methods of hauling cotton to the gins, its subsequent ginning and baling, and its handling and storage in the yards. Inquiries were also made to determine the advisability of marketing Durango cotton directly to the spinning mills at prices equal to those obtained by growers of staple cotton in the Mississippi Delta and elsewhere.

A brief discussion is given of the transportation facilities and rates for all classes of cotton grown in the Imperial Valley.

Foxtail millet.—Its culture and utilization in the United States, H. N. VINALL (U. S. Dept. Agr., Farmers' Bul. 793 (1917), pp. 28, figs. 10).—This is a general discussion of the kinds, production, and utilization of millets grown in the United States.

A comparison of varieties, based on data compiled from experiment station tests in various sections of the country, indicates that the German and Hungarian millets are best adapted to humid regions, with the Kursk and Common for the dry northwestern plains. Analyses reported show that the feeding value of the hay of foxtail millet is approximately the same as that of timothy, although injury has resulted from a continuous ration of millet hay for horses.

These millets are utilized chiefly as a catch crop in the United States, and are especially valuable in the semiarid regions because of their short growing season. They are reported as being remarkably free from plant diseases.

Potato growing in Colorado, E. P. Sandsten (Colorado Sta. Bul. 220 (1917), pp. 3-29, pl. 1, figs. 7).—This is a general discussion of the cultural methods and field practices employed in potato production in Colorado, including data on potato diseases.

[Field experiments with potatoes at the Jerome substation], G. W. Dewey (Idaho Sta. Bul. 92 (1916), pp. 55-57).—Irrigation and cultural experiments with potatoes are reported. The latter included the testing of greened v. ungreened seed, foreign v. homegrown seed, mature v. immature seed, and cut v. whole seed.

Greened Idaho Rural seed produced 41.1 bu., or 17.9 per cent, per acre more than the ungreened. Greened Netted Gem produced 19 bu., or 10.8 per cent, more than the ungreened. Seed exchanged with the Greeley (Colo.) substation outyielded the home-grown seed at Jerome by 25.6 bu. (Idaho Rural variety) and 18 bu. at Greeley (Netted Gem variety). Plants from immature seed developed 4.8 per cent of curly dwarf, while those from mature seed developed 37.6 per cent. Idaho Rural grown from immature seed yielded 59.7 bu., or 16.7 per cent, more per acre than that grown from mature seed, while with the Peoples variety the immature seed yielded 88.7 bu., or 29.5 per cent, more than the mature seed.

One hundred potato varieties were introduced from South America and grown during the 1916 season, but only two are to be tested further.

The management of tobacco soils, J. Johnson (Wisconsin Sta. Bul. 277 (1917), pp. 2-29, figs. 12).—This is a general discussion of the preparation and

cultivation of tobacco soils, with special reference to the maintenance of soil fertility. The decreased yield and quality of tobacco grown on "sick" soils, due to the presence of the root rot disease (*Thielavia basicola*), is emphasized and control measures recommended.

A study of Colorado wheat, III, W. P. Headden (Colorado Sta. Bul. 219 (1916), pp. 3-131).—In continuation of previous work (E. S. R., 35, p. 832), the author presents data relative to the composition of Colorado wheats in general, and the results of studies of the effects of fertilizers, of water, and of climate upon the composition of wheat. Defiance, Red Fife, and Kubanka wheats grown in the seasons of 1913, 1914, and 1915 under known conditions form the basis for the analytical results obtained.

The results served to show that Colorado wheats contain large percentages of nitrogen and of true gluten. The ratio of gliadin nitrogen to glutenin nitrogen falls well within the limits accepted for good flours. On the other hand, some samples were low in nitrogen but had a fair gliadin-glutenin ratio. Samples grown under dry-farm conditions were not found to be superior to those grown under irrigation.

The factors which determine the wheat crop are given as distribution of rainfall rather than quantity, the degree of cloudiness, resistance of the plant to rust, the stage of development of the plant when attacked, temperature, and soil fertility.

The character of the wheat grain is deemed much more easily influenced by soil fertility than is generally supposed, and the individual plant food elements exercise specific influences upon its composition. The nitric nitrogen in the soil affects the growth of the plant, increasing the nitrogen content of both the plant and the seed. Nitric nitrogen also influences the composition and character of the grain, producing the characteristic "hard" wheat. These characters are believed to have a deeper significance in the plant metabolism than the production of an increase of a few tenths of one per cent in the nitrogen content of the berry. The mineral constituents contained in the berry are influenced by the amount of nitric nitrogen available to the plant, as are those in the plant itself, but in the latter instance to a different extent and not necessarily in the same direction as in the berry. Furthermore, nitric nitrogen produces a soft, weak straw, causing lodging both from a production of a heavy growth of leaves and elongation of the upper parts of the plant and from a weakness in the lower nodes. It also greatly increases susceptibility to rust, probably by furnishing a better nutrient and because of the softened condition of the plant. Organic nitrogen in farmyard manure does not produce these results, except as it is converted into nitric nitrogen, the rate of which process depends upon the nitrifying power of the individual soils.

The investigations with potassium indicate that that element has no positive effect on the quantity of starch produced. Potassium has a tendency, however, to suppress the nitrogen content of the berry, and it suppresses that of the plant, particularly in the stems and leaves, throughout its growing period, but does not appear to suppress that of the head. Potassium stimulated growth at a certain stage of development, but the plants on the other plats attained the same degree of development a few days later. It apparently increases yellow berry.

Phosphorus has produced no definite effect. The phosphorus in the berry was depressed by nitric nitrogen but was not affected by potassium.

Manganese was uniformly present.

The amount of irrigation water applied may increase yields but has practically no effect upon the composition of the crop. The leaching effect of irrigation water on the nitrates is not sufficient to affect the nitrogen content

39

of the plant if applied two months after the use of the nitrates. Frequent light rains, together with heavy dews, produce different effects from irrigation. The time of rainfall and weather conditions following are of great but indirect importance, depending upon the development of rust.

Just before maturity, the plant transfers its substance to the berries and the effect of rust is to inhibit this transfer. Rust causes a marked depression in the protein content of the wheat, even if the crop is well developed at the time of attack. Rust also increases the percentage of crude fiber in the wheat by preventing the filling out of the berries.

There exists an optimum ratio between nitric nitrogen and available potassium in the soil. If potassium predominates, yellow berry is produced, while, if nitric nitrogen predominates, soft, weak plants and small, flinty, and often shrunken berries result.

In regard to crushing strength, Colorado wheats range from semihard to hard. The general composition of these wheats is above the average but undergoes considerable variation due to soil and other immediate causes, but not as a rule to climatic conditions.

Nitrogen fixation proceeds rapidly enough, in the soils studied, to furnish an amount of nitrogen sufficient to become an important factor in these problems. Furthermore, nitrification proceeds rapidly enough to more than quintuple in five months the nitrate nitrogen in the soil at harvest time.

The analytical methods employed by the author are abstracted on page 11. Dry-farmed and irrigated wheat, J. S. Jones, C. W. Colver, Amy Kelly, and Elizabeth Hays (Idaho Sta. Bul. 88 (1916), pp. 18).—This reports analytical and baking tests with samples of dry-farmed and irrigated wheat grown in southern Idaho during 1912, 1913, and 1914, for a comparison of the quality of wheat so produced and as supplementary to work previously noted (E. S. R., 27, p. 266).

From an analysis of the mill products of 79 samples of dry-farmed wheat and 60 samples of irrigated wheat, two things are outstanding in the Bluestem and Turkey Red varieties, the two varieties which seem to be most commonly grown on both dry and irrigated farms. These are (1) the lower yield of flour from the soft wheat, and (2) the lack of any decided difference between dry-farmed and irrigated Bluestem and dry-farmed and irrigated Turkey Red in the percentage of flour obtained. The average gain in milling for all dry-farmed samples was 1.17 per cent and for all irrigated samples 1.12 per cent.

Additional data are presented showing the weights per bushel and per thousand kernels for all wheat samples, together with the percentages of moisture, ash, ether extract, and protein for all wheat and flour samples and the percentages of gluten (wet and dry) and of gliadin for all flour samples. In a comparison of Bluestem and Turkey Red samples the irrigated samples are slightly heavier in weight per bushel, while in weight per thousand kernels the difference is more pronounced, especially in Turkey Red. moisture, ash, and ether extract of both wheat and flour show no differences that would serve to identify them with the system of farming under which they were produced. There was an average difference between the flours of dry-farmed and irrigated Bluestem of only 0.38 per cent of protein, 2.35 per cent of wet gluten, and 1.06 per cent of dry gluten, while those of the average dry-farmed and irrigated Turkey Red wheats show a difference of 2.79 per cent protein, 9 per cent wet gluten, and 2.24 per cent dry gluten, all differences being in favor of the dry-farmed samples. The ratio of wet to dry gluten in both dry-farmed and irrigated Bluestem is 2.9, in dry-farmed Turkey Red 3.2, and in irrigated Turkey Red 3. Since the relative strength

of flours is believed to be indicated by the relative amounts of water their glutens absorb, flour from dry-farmed Turkey Red would by this test be slightly superior to that from irrigated Turkey Red.

The dry-farmed samples were higher in weight per bushel by 0.4 lb., in protein of grain by 1.8 per cent and of flour by 1.47 per cent, in wet gluten by 2.86 per cent, and in dry gluten by 1.68 per cent, and lower in weight per thousand kernels by 1.68 gm. The ratio of wet to dry gluten was 2.8 and 2.9, respectively.

The results of the baking tests are reported in tabular form, showing the amount of water absorbed per 340 gm. of flour, the weight and volume of baked loaf, and the score obtained on the various points considered. Dryfarmed Bluestem produced higher-scoring loaves than irrigated Bluestem, while irrigated Turkey Red produced higher-scoring loaves than dry-farmed Turkey Red. The product of varieties grown under irrigation only scored 3.4 points higher than that from varieties grown under dry-farm conditions only. The average score of all loaves (71) representing all dry-farmed samples was 0.7 point lower than that of all loaves (51) representing all irrigated samples.

It is concluded that, from the standpoint of home baking, insistence for brands of flour milled from the better varieties would do more to raise the flour standards of the State than discrimination in favor of either dry-farmed or irrigated products. Moreover, these results indicate that large differences in gluten percentages are not sharply reflected in results secured from different flours under home-baking conditions. These conclusions are in accord with those arrived at previously.

Commercial agricultural seeds, 1916, C. D. Woods (Maine Sta. Off. Insp. 81 (1917), pp. 28).—Tables are given showing the results of the 1916 seed inspection, together with a list of the weed seeds found.

### HORTICULTURE.

[Report of the] department of horticulture, H. P. STUCKEY (Georgia Sta. Rpt. 1916, pp. 16-18).—A brief progress report on horticultural work for the year, including some records of peach trees planted in the spring of 1914 and receiving different fertilizer treatments during 1915 and 1916.

[Some results of horticultural work] (Iowa Sta. Rpt. 1916, pp. 32-34).—A popular summary of results secured from horticultural work conducted under the direction of the Iowa Station, including results of grape pruning and apple spraying tests.

[Report on horticultural investigations] (New Mexico Sta. Rpt. 1916, pp. 27-31).—A brief progress report on the station's various horticultural projects.

A table is given showing the results of pear pollination work for the year. Experimental grafts of apple scions on pear stocks have apparently made strong unions. In case of the Delicious apple the fruit grown on pear stocks holds on the branches much better than that grown on apple stocks.

One noticeable feature of the fertilizer experiment with peach trees, which was completed during the year, was the material decline of trees heavily fertilized with barnyard manure. Previously the growth of these trees had been vigorous although the fruit was inferior in quality and color. The fruit during the past year was too small to pick and the manured trees were attacked by chlorosis more severely than the unfertilized trees.

[Report of the] division of horticulture (Washington Sta. Bul. 136 (1917), pp. 42-44).—Tests were made in some 50 orchards, part of which were given clean tillage and part planted to alfalfa or red clover for three years or more to ascertain whether the alkali content of the soil is appreciably modified by

growing these crops. Analyses secured indicate that the alkali content of the soil to a depth of 2 ft. was reduced only 0.002 per cent and that the humus and volatile content of the soil was increased only 0.03 per cent in the cover crop orchards. Observations relative to the relation of winter injury to rosette indicate that winter injury of the trunk and larger limbs does not as a rule occur in rosetted orchards but is most frequent in those free from that trouble.

Work upon the relation of soil moisture to the keeping quality of Jonathan and Rome Beauty apples showed very little difference in the date of ripening upon plats which received 12, 9, and 6.6 per cent of water, respectively. The large-sized fruits of any variety ripened first regardless of the moisture conditions.

A study of orchard cover crops has shown that peas and vetch produce a slightly better physical condition of the soil than such crops as oats, wheat, and rye. In some experiments in the renovation of prune orchards in Clarke County it has been found that great improvement in the production and quality of prunes was secured by the use of lime and nitrogen fertilizers.

In connection with a variety test of potatoes it was found that the character of the seed storage has much to do with the stand of plants produced.

Hotbeds and cold frames, T. F. LIMBOCKER (Colorado Sta. Bul. 221 (1917), pp. 8, figs. 4).—Popular directions are given for the construction and management of hotbeds and cold frames.

[Experiments with tomatoes and cucumbers] (Expt. and Research Sta., Waltham Cross, Ann. Rpt., 2 (1916), pp. 7-28).—The results are given for one season of fertilizer, management, and cultural experiments with tomatoes and cucumbers in the greenhouses at the Experimental and Research Station of the Nursery and Market Garden Industries' Development Society, Limited, Waltham Cross, Herts, England.

Fruit growing for amateurs, H. H. Thomas and J. Gardner (London and New York: Cassell & Co., Ltd., 1916, pp. VII+152, figs. 129).—A popular treatise on the culture, management, and home conservation of orchard and small fruits.

Fruit varieties for Maine, B. S. Brown (Univ. Maine Ext. Bul. 111 (1917), pp. 19).—This comprises a varietal list of orchard and small fruits recommended for planting in Maine.

A valuable unpublished work on pomology, P. L. RICKER (Science, n. scr., 44 (1916), No. 1124, pp. 62-64).—The author here announces the donation by the grandchildren of Elizabeth (Coxe) McMurtrie to the library of the U. S. Department of Agriculture of a bound collection of colored drawings of the fruits that were illustrated by woodcuts in A View of the Cultivation of Fruit Trees of America, published in 1817 by William Coxe. The drawings are accompanied by the bound manuscript upon which the published work was based, to which have been added numerous notes intended for a second edition.

The pruning manual, L. H. Bailey (New York: The Macmillan Co., 1916, 18. ed., rev., pp. XIII+407, figs. 381).—The present edition of this work (E. S. R., 11, p. 152) has been revised to include the results of recent investigations on the subject of pruning. The author points out, however, that very few of the pruning experiments in different places are really comparable with each other, and do not warrant the relinquishment of much of the traditional practice which is often the result of accumulated experience.

Pruning problems in the Hood River Valley, G. G. Brown (Oregon Sta. Bul. 141 (1917). pp. 48-54, figs. 2).—A discussion of pruning practices with special reference to the Hood River Valley and based upon pruning investigations conducted at the Oregon Station.

Influence of commercial fertilizer upon the bearing apple tree, C. I. Lewis and G. G. Brown (Oregon Sta. Bul. 141 (1917), pp. 37-47, figs. 2).—In the pre-

vious report (E. S. R., 35, p. 540), it was pointed out as a result of two seasons' experiments that nitrate of soda had a decidedly beneficial effect upon the vigor and production of devitalized apple trees. In the present paper the results of previous experiments are summarized and additional data are given on these experiments, together with the results secured from two more orchards treated with the nitrate in 1916. No fertilizer was applied in 1916 to the orchards receiving nitrate in 1914 and 1915. In one of the orchards a crop of clover was turned under and in the other alfalfa and clover were allowed to grow.

The observations for the season indicate that the invigorating influence of nitrate of soda has continued into 1916 and gives good promise for the following season. Beneficial results from nitrates were also secured on the orchards treated for the first time in 1916. The results of the experiments as a whole indicate that nitrate of soda is valuable as a means of rapidly renewing the vigor and production of devitalized apple trees. It is pointed out, however, that the beneficial effects of shade or cover crops in restoring nitrogen and humus should be understood. In case of unsatisfactory growth nitrate of soda in small quantities might be found useful in rotation with shade crops.

Experimental dusting and spraying of peaches, W. W. Chase (Ga. Bd. Ent. Circ. 21 (1917), pp. 14, pls. 4).—This circular summarizes the results of three seasons' experiments in dusting peaches with lead arsenate and sulphur preparations, conducted by the Georgia State Board of Entomology.

The use of dust mixtures has resulted in almost perfect control of peach scab, brown rot, and curculio; good coloring of fruit; thorough and uniform distribution of material; saving of time, labor, teams, and initial cost of equipment as compared with liquid spraying; independence of water; and little deterioration of dusting mechanism and none of material. The dusting method has a tendency to burn leaves, defoliate the trees, and crack or check the flesh of the fruit when applied too heavily. This is more marked when the application is closely followed by rain. It is suggested that the use of improved machinery, better methods of application, accurate regulation of output, and modification of formulas may reduce this type of injury to negligible quantities.

What the experiment station peach orchard has cost and what it has produced, C. A. McCue (Del. Farmer, 4 (1916), No. 2, pp. 25-28, fig. 1).—A popular summary of the subject matter in Bulletin 113 of the Delaware Station (E. S. R., 36, p. 42).

Experimental investigations of the plum (Prunus domestica).—I, Agricultural chemical statistics and the composition of the fruit, D. Feruglio (R. Lab. Chim. Agr. Udine, Ric. Sper. e Attiv. Spiegata, 4 (1911–1914), pp. 99–110, pls. 2).—This is the first of a series of notes dealing with the plum and its culture. It gives a brief review relative to the importance of the plum industry in Europe, particularly in Italy, together with analytic data showing the physical and chemical composition of the fruit, as well as the chemical composition of the seed, foliage, annual shoots, and the estimated amount of various plant foods annually removed by plum trees.

Strawberry growing, S. W. Fletcher (New York: The Macmillan Co., 1917, pp. XXII+325, pls. 24, figs. 28).—The aim of the present work is to reflect modern commercial practice in North America. The successive chapters discuss locations, sites, and soils; planting; rotations, manuring, and fertilizing; tillage and irrigation; training the plant; mulching; pollination; packages; picking and packing; marketing; cost of production, yields, and profits; propagation and renewal; everbearing varieties, forcing and other special methods

of culture; insects, diseases, and frost; varieties; and statistics on acreage, production, and value.

The forcing of strawberries, Florence I. Kinnison (Colorado Sta. Bul. 222 (1917), pp. 8, figs. 2).—The forcing experiment with strawberries, here described, was conducted with the view of studying the cultural methods and the best varieties for forcing.

Marshall and Glen Mary proved to be the best two varieties for forcing, the former being used as a pollenizer for the latter. New crowns produced a heavier yield and larger and better berries than old ones. It is concluded that forcing strawberries can be made profitable with the berries selling at 25 cts. a half a pint.

Marketing and distribution of strawberries in 1915, O. W. Schleussner and J. C. Gilbert (U. S. Dept. Agr. Bul. 477 (1917), pp. 32, pls. 4, flgs. 10).—A review of the 1915 strawberry season in the United States, based upon observations made by the authors at shipping points and by members of the staff working in the markets. The subject matter is presented under the general headings of methods employed in dealing with strawberry pickers; cooperative associations; sales methods commonly employed; transportation; a study of the Louisiana district; extent, length, and volume of movement from all districts; comparison of prices received for strawberries on important markets; average quality of strawberries shipped; distribution of strawberries in 1915; and total strawberry shipments in 1915. In addition to tabular data given, the distribution and total strawberry shipments from various sections is illustrated by charts.

Behavior of the root system of various graft stocks, L. Ravaz (Prog. Agr. et Vit. (Ed. VEst-Centre), 38 (1917), No. 10, p. 227).—The author gives some tabular data showing the average number and size of roots of various American grape stocks used in vineyard reconstitution. In certain stocks it is observed that the number of roots is always few but they are generally large and long, whereas in other stocks the roots are very numerous, small, and short.

Oil percentage in different varieties of olives, H. E. LAFFER (Jour. Dept. Agr. So. Aust., 20 (1917), No. 7, pp. 548, 549).—Analyses for one season are given showing the oil percentage in 13 different varieties of olives growing at the Roseworthy Agricultural College. The oil content of the fresh olives ranged from 11.51 to 27.29 per cent.

Citrus fertilization experiments in Porto Rico, C. F. Kinman (*Porto Rico Sta. Bul. 18 (1917)*, Spanish Ed., pp. 34, pls. 2, figs. 2).—The English edition of this bulletin has been previously noted (E. S. R., 33, p. 241).

Some profitable and unprofitable coffee lands, T. B. McClelland (Porto Rico Sta. Bul. 21 (1917), pp. 13, pls. 2, figs. 5).—This bulletin, which is based upon studies of Porto Rican coffee soils extending over a number of years, gives specific instances in which coffee is being grown on lands suited for coffee culture and on lands unsuited for coffee culture, together with information relative to the selection of good coffee lands and the improvement of poor lands when they are to be used for growing coffee. It is pointed out, however, that many of these poorer soils should be devoted to pasture or forests or some other crop for which the land may be better adapted.

What tea planters can and must do for selection, C. P. C. STUABT (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Proefstat. Thee, No. 48 (1916), pp. 22).—The author reviews the work of the Buitenzorg tea station in the development of improved strains of tea, and outlines practical selection investigations which must be conducted by the planters in order to render the selection work of practical value.

Investigations on the process of tea fermentation as conducted in the Malabar Laboratory, K. A. R. Bosscha and A. Bezesowsky (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Proefstat. Thee, No. 47 (1916), pp. 40, pl. 1, figs. 10).—An account is given of investigations relative to the various microorganisms occurring on tea leaves and the fermentation of tea with and without the presence of these microorganisms. A bibliography of cited literature is given.

The authors conclude in substance that although the process of tea fermentation progresses hand in hand with the development of micro-organisms on the tea leaves it is independent of the presence of these micro-organisms. Fermentation does not progress successfully above a certain critical temperature. The present experiments indicate this temperature to be from 43 to 43.5° C. (109.4 to 110.3° F.). Likewise, fermentation will not take place in an atmosphere deprived of oxygen. The experiments do not show, however, whether fermentation is brought about by the action of the ferment present in the tea or by oxidation of the constituents of the tea through the oxygen of the atmosphere.

Report on varieties of pecans for 1914, 1915, and 1916 at the Georgia Experiment Station, H. P. STUCKEY (Georgia Sta. Circ. 76 (1917), pp. 3).—In continuation of previous records on the varieties of pecans grown at the station orchard (E. S. R., 34, p. 151), this circular records the behavior of the trees during the years 1914, 1915, and 1916.

Breeding for atropin, L. W. Arny (Jour. Heredity, 8 (1917), No. 4, pp. 164-167, fig. 1).—Preliminary observations on  $F_1$  belladonna seedlings suggest that size of plant at the harvest period in connection with color of stem may be an index to the relative atropin content of the plant. In the present work high-yielding plants were small, with light stems, and low-yielding plants were large and vigorous, with dark stems. Observations are to be continued on selected  $F_2$  plants.

Planting the home grounds, J. H. McFarland (Harrisburg, Penn.: The Countryside Press, 1915, pp. 70, figs. 29).—A popular treatise on planning and planting the home grounds, including lists of plants recommended for various purposes.

Decorative shrubs and trees, E. L. Wolf (Dekorativnye Kustarniki i Derev'a dla Sadov i Parkov. Petrograd: A. F. Devrien, 1915, pp. XI+462, pl. 1, figs. 203).—A treatise on the selection, planting, and care of ornamental trees and shrubs, including lists of varieties recommended for different purposes.

How to grow chrysanthemums, J. CLAYTON (London: The Cable Printing and Publishing Co., Ltd. [1917], pp. 4+97, pls. 4).—A practical guide for beginners, giving details for growing chrysanthemums in the greenhouse and in the open.

### FORESTRY.

The correlation of American forest research, E. H. CLAPP (Jour. Forestry, 15 (1917), No. 2, pp. 165-175).—In this paper the author gives a general summary of research investigations of the Forest Service of the U. S. Department of Agriculture and calls attention to research work being conducted by certain States and private foresters and to the importance of securing correlation of the forest research work carried on by all agencies in the United States.

Sixteenth annual report of the State Board of Forestry, 1916, E. A. GIADDEN (Ann. Rpt. Ind. Bd. Forestry, 16 (1916), pp. 217+V, figs. 107).—In addition to a report on activities on the State forest reservation, descriptive lists are given of native trees found on the State forest reserve and native trees of

Indiana planted in the park at the reserve, together with a general list of trees and shrubs in the park. Some miscellaneous papers dealing with woodlot problems and forest planting are also included.

Report of the department of forestry of the State of Pennsylvania for the years 1914-15, R. S. Conklin (Rpt. Penn. Dept. Forestry, 1914-15, pp. 247, pls. 17).—A report of the department of forestry for the years 1914 and 1915, reviewing forest protection work, development work and operations on the State forests and nurseries, lumbering operations, timber sales, surveys, etc.

Report of the committee on forests, C. Leavitt (Com. Conserv. Canada Rpt., 7 (1916), pp. 41-52, pls. 2).—A short résumé of recent activities in forestry and fire protection in Canada.

Progress report on forest administration in the Northwest Frontier Province for the year 1915-16, R. Parnell (Rpt. Forest Admin. North-West Frontier Prov., 1915-16, pp. 3+II+18+XXV).—The usual progress report on the administration of the State forests in the Northwest Frontier Province, including a financial statement for the year 1915-16. All important data relative to alterations in forest areas, forest surveys, working plans, forest protection, miscellaneous work, revenues, expenditures, etc., are appended in tabular form.

Progress report of forest administration in Baluchistan for 1915-16, MULRAJ (Rpt. Forest Admin. Baluchistan, 1915-16, pp. II+28).—A report similar to the above relative to the administration of the State forests in Baluchistan for the year 1915-16.

Ecology and silviculture in the southern Appalachians: Old cuttings as a guide to future practice, E. H. Frothingham (Jour. Forestry, 15 (1917), No. 3, pp. 343-349).—A paper on this subject presented at the New York meeting of the Ecological Society, December 28, 1916.

Reforesting Pennsylvania's waste land.—What and how to plant, W. G. CONKLIN (Penn. Dept. Forestry Bul. 15 (1916), pp. 34, pls. 19).—This bulletin contains practical suggestions for reforesting waste lands in Pennsylvania, based upon operations on the State forests.

Silvicultural problems on forest reserves, B. E. Fernow (Com. Conserv. Canada Rpt., 7 (1916), pp. 66-74).—This paper reviews a number of the difficulties that are encountered in practicing the art of producing forest trees, with special reference to conditions in Canada.

Some problems in light as a factor of forest growth, R. Zon (Jour. Forestry, 15 (1917), No. 2, pp. 225-232).—In this paper the author calls attention to important phases in the study of light that deserve particular consideration by the forester, and outlines tests for determining the effect of soil fertility upon shade endurance of forest trees and the effect of heat upon the tolerance of forest trees.

The rôle of light in natural and artificial reforestation, C. G. Bates (Jour. Forestry, 15 (1917), No. 2, pp. 233-239).—The author briefly reviews the literature of the subject, and reaches the conclusion that "if we are to obtain a solution of the problems which are conceived in the terms 'tolerance' and 'intolerance,' and if we would give quantitative expression to the requirements of the various species of light we must consider this factor in its full meaning of radiant energy; we must consider the physical value of radiant energy rather than its chemical value; and finally we must determine its effective physical value in combination with the heat of the air rather than its theoretical physical value."

Seeding habits of spruce as a factor in the competition of spruce with its associates, L. S. Murphy (*Plant World*, 20 (1917), No. 3, pp. 87\*90).—A short contribution on this subject, based on observations made in the fall of 1910

and the spring of 1911 and offered with the view of calling attention to a promising field of research.

A practical method of preventing the damping-off of coniferous seedlings, C. A. Scott (Jour. Forestry, 15 (1917), No. 2, pp. 192-196, pls. 2).—The author here describes a practical method of sterilizing forest nursery seed beds with high pressure steam to reduce the loss of evergreen seedlings by damping-off. This method was recently developed with successful results at the Kansas Experiment Station.

The windbreak as a farm asset, C. G. Bates (U. S. Dept. Agr., Farmers' Bul. 788 (1917), pp. 15, flgs. 8).—This publication discusses windbreaks with special reference to their use in protecting the fields and farm buildings from the force of the wind, including planting instructions and kinds of trees recommended for planting in different sections. Estimates are also given of financial returns per acre to be expected from various kinds of windbreaks.

To determine the total effect, whether beneficial or injurious, of windbreaks on crop yields a number of crop measurements were made in Nebraska, Kansas, Iowa, and Minnesota. The measurements as a whole indicate that with ordinary field crops the farmer may count on a benefit from windbreak protection which will make the loss of the area occupied by the trees negligible.

Timber estimating in the southern Appalachians, R. C. Hall (Jour. Forestry, 15 (1917), No. 3, pp. 310-321).—In this paper the author discusses methods employed in estimating timber and approving forest lands for purchase under the so-called Weeks Law, together with new adaptations which have proved especially valuable.

Some problems in Appalachian timber appraisal, W. W. Ashe (Jour. Forestry, 15 (1917), No. 3, pp. 322-334).—A paper somewhat similar to the above discussing problems in timber appraisal work peculiar to the Appalachian forests.

The rôle of the microscope in the identification and classification of the "timbers of commerce," I. W. Bailey (Jour. Forestry, 15 (1917), No. 2, pp. 176-191, pls. 3, figs. 2).—In this paper the author concludes that anatomical keys for distinguishing woods as constructed by botanists and microscopists have failed to receive the recognition and extended use that have commonly been predicted for them. Two important reasons for this failure, as here discussed, are limitations to the use of anatomical keys in the lumber business and variability of anatomical characters. A careful study of some of the supposedly most reliable diagnostic criteria, such as the distribution of wood parenchyma, form and structure of the rays, type of pitting, etc., indicates very clearly that these characters may fluctuate considerably, not only in certain families, genera, and species, but also in different parts of a single tree.

### DISEASES OF PLANTS.

[Report of the division of botany.—Bacteriology and pathology] (Washington Sta. Bul. 136 (1917), pp. 19-25, figs. 3).—A progress report is given of some of the more important investigations being carried on by the division of botany. Among these are studies of tomato blight, previous notes of which have been given (E. S. R., 36, p. 350); identification of fungus diseases; investigations of fire blight, an account of which has already been noted (E. S. R., 35, p. 848); and wheat smut, also previously noted (E. S. R., 34, p. 644).

In connection with the wheat smut investigations, two sources of infection have been discovered, the first from spores adhering to the wheat grain and infecting at the time of sprouting, the second from the spores which settle upon number fallow ground during the thrashing season. In the prevention of this

disease, for the first method of infection soaking the seed in copper sulphate or formaldehyde solution is recommended, and for the second method of infection either early sowing of wheat before the thrashing season has begun or late sowing after the smut spores scattered over the soil have germinated. In these investigations an automatic sprinkler has been devised and perfected by the station for use in connection with thrashing outfits.

[Plant diseases in 1915] (Phytopath. Lab. "Willie Commelin Scholten" Jaarver. 1915, pp. 18).—The report on plant diseases and investigations deals with injuries to fruit trees due to Hymenomycetes, anthracnose of flax, narcissus diseases, Botrytis on flowers, potato mosaic, and Rhizoctonia (Hypochnus) solani on potato.

Plant protection, F. G. STEBLER (Landw. Jahrb. Schweiz, 30 (1916), No. 1, pp. 20-23).—This is a very condensed account dealing with the spring condition of cereals; diseases and protection of cereals, potatoes, beets, and legumes; and various wild plants, or weeds, as noted at the Zurich Experiment Station.

Studies in tropical teratology, J. C. Costerus and J. J. Smith (Ann. Jard. Bot. Buitenzorg, 2. ser., 14 (1916), pt. 2, pp. 83-94, pls. 5).—The authors have here described a number of monstrosities, including witches' broom, as observed in plants representing a wide range of classification, the specimens examined having been from Buitenzorg.

Studies in the physiology of parasitism.—II, Infection by Botrytis cinerea, V. H. BLACKMAN and E. J. WELSKORD (Ann. Bot. [London], 30 (1916), No. 119, pp. 389-398, pl. 1, figs. 2).—This is in continuation of the series of contributions begun by Brown (E. S. R., 34, p. 847).

Vicia faba was studied regarding its capacity for infection by B. cinerea. Infection was readily accomplished when the leaf surface was moistened with turnip juice. The germ tube soon develops a mucilaginous layer by which it appears to be so firmly anchored to the cuticle that its tip can bend in and penetrate the cuticle with a peglike outgrowth, apparently by mechanical pressure alone. No swelling or other change in the cuticle or in the underlying epidermal layers prior to penetration has been observed, but as soon as the cuticular layer is passed a swelling of the subcuticular layer occurs, showing enzym action. Penetration of the cuticle by the germ tube was not preceded by death of epidermal cells, but swelling of the latter preceded the disorganization of the protoplast. No microscopic evidence was found for the secretion of a special toxic substance other than the enzym for dissolving the cell wall.

Studies in the physiology of parasitism.—III, On the relation between the "infection drop" and the underlying host tissue, W. Brown (Ann. Bot. [London], 30 (1916), No. 119, pp. 399-406).—It is stated that the results of this purely physiological study, as here detailed, are in exact agreement with the results of the microscopical study, as above noted, by Blackman and Welsford.

On the osmotic pressure of the tissue fluids of Jamaican Loranthaceæ parasitic on various hosts, J. A. Harris and J. V. Lawrence (Amer. Jour. Bot., 3 (1916), No. 8, pp. 438-455, figs. 2).—Data gathered from a study of materials obtained in 1915 near Cinchona, in the Blue Mountains of Jamaica, employing seven species of Loranthaceæ in three genera parasitic on nineteen species of host, are presented. The authors claim that stem sap from the leafless species of Dendrophthora has a lower osmotic pressure than that from leaf tissue of Phoradendron or Phthirusa, also that the osmotic pressure of the sap from the chlorophyll-bearing tissue of the parasite is almost always greater than in that from the mature leaves of the host.

The fungicidal properties of certain spray fluids, J. V. EYBE and E. S. SALMON (Jour. Agr. Sci. [England], 7 (1916), No. 4, pp. 473-507).—In the hope of ascertaining to what particular factor the fungicidal value of alkaline sul-

phid solutions should be attributed, the authors carried out a study during 1914 and 1915 with powdery mildews (Erysiphaceæ), the materials and methods of which are discussed in detail.

Such fungicides as liver of sulphur and ammonium sulphid when used against powdery mildews require some such substance as soft soap to insure adequate wetting of the foliage by the spray. Liver of sulphur was not effective when used at concentrations below 0.6 to 0.8 per cent. Yellow ammonium sulphid proved to be efficacious against hop mildew in the greenhouse and against American gooseberry mildew in the open. Unlike lime sulphur it leaves no disfiguring deposit, and at definite fungicidal strength it does not scorch the foliage. Iron sulphid at 0.6 per cent quickly destroys hop mildew. When so made as to contain a trace of ammonium sulphid, it is in a condition in which it can be reduced to a fine spray and is harmless.

Free alkali is not the determining fungicidal factor in alkaline sulphid solutions, nor is the proportion of sulphid sulphur present an index of their fungicidal value. Apparently the polysulphids in yellow ammonium sulphid act fungicidally as such, and not by virtue of the sulphur deposited when they decompose.

The effect of covering winter crops, L. Hiltner (Prakt. Bl. Pflanzenbau u. Schutz, n. ser., 14 (1916), No. 1, pp. 3-10).—A report is given of experiments conducted in 1914-15 to determine the effect of mechanical winter covering of cereals on the development of Fusarium diseases. Most of the experiments were carried out with winter rye, although winter wheat and clover were also tested. Seed treated with formaldehyde and untreated seed were employed, the mechanical coverings being straw, manure, various chemical fertilizers, etc. The results for rye are tabulated, marked varietal differences due to the treatment being noted. In practically every instance the harvest was greatest from the treated seed.

The general conclusion drawn from the experiments is that any form of covering, even snow when the ground is unfrozen, is injurious when Fusariums are present, as it produces conditions favorable for the development of the fungus.

Notes on some diseases of collards, B. B. Higgins (Georgia Sta. Rpt. 1916, pp. 21-27, flys. 6).—Attention is called to black mold of collards due to Alternaria brassica, which is said to have been very destructive during several years. The fungus attacks the more tender parts of the plant, causing their destruction, and in many instances it is associated with soft rot bacteria which enter through the fungus lesions. As a result of observations, it was suspected that the harlequin bug plays an important part in the spread of the disease and this suspicion was confirmed by investigations carried on in 1916. In connection with the study of the rôle of this insect in spreading the disease, an investigation was made to determine whether the fungus entered through insect punctures, but all the evidence obtained seemed to indicate that the germ tube of the fungus entered through the stomata of the plant. For the control of this disease, one or two applications of Bordeaux mixture are recommended, though no experiments in control have been undertaken. The destruction of harlequin bugs is also considered important.

In addition to the above disease, Sclerotinia libertiana also attacks collards, considerable damage being done, especially to young plants.

A new sweet corn disease in Kentucky, H. Garman (Kentucky Sta. Circ. 13, pp. 4, fig. 1).—A description is given of a destructive bacterial disease attacking sweet corn, first noted at the Kentucky Station in June, 1916. The disease is considered the same as that previously described by Stewart (E. S. R., 9, p. 1056). In addition to the usual characteristics of this disease, the author

describes a soft rot occurring at the base of the cornstalk, which is thought to be due probably to the admission of other bacteria. Since the disease is known to be conveyed with the seed corn, the importance of obtaining seed from non-infested regions is pointed out.

Dissemination of the angular leaf spot of cotton, R. C. FAULWETTER (U. S. Dept. Agr., Jour. Agr. Research, 8 (1917), No. 12, pp. 457-475, pl. 1, fig. 1).—
The author presents data obtained during the summer of 1916 at the South Carolina Experiment Station on the dissemination of the angular leaf spot of cotton. He also suggests that the factors recognized as concerned in the dissemination of this disease may also have an important bearing on the spread of other diseases.

Studies were made of insect carriers, seed-borne infection, winds, etc., in relation to this disease, and the author concludes that much of its spread, under the conditions of his experiments, was due to the carrying of bacteria from infected plants by wind-blown rain. This conclusion is largely drawn from observations on the dissemination of the disease from inoculated plants following two severe storms in July, in which high winds were accompanied by heavy rains. The spread of the disease from the artificially inoculated plants was determined to be in the direction of the prevailing winds during these storm periods. Insects are considered as playing a very unimportant rôle, while seed dissemination aside from its primary infection is not believed to be important.

Peanut wilt caused by Sclerotium rolfsii, J. A. McCLINTOCK (U. S. Dept. Agr., Jour. Agr. Research, 8 (1917), No. 12, pp. 441-448, pls. 2).—An account is given of observations and investigations conducted at the Virginia Truck Experiment Station to determine the cause and methods of control of the wilt disease of peanuts first observed at the station in the summer of 1915.

The disease appears under field conditions when the plants are from one to two months old and continues to develop throughout the season. The fungus attacks the shoots at or near the surface of the soil, killing the invaded tissues. Wilted plants have been observed scattered over the entire area of each plat, indicating that the causal organism is well distributed. Isolation and inoculation experiments have shown the pathogenicity of the causal organism and established its identity as *S. rolfsii*.

In a test of six varieties of peanuts and one of the so-called hog goober (Voandzeia subterranea) marked differences were observed in susceptibility to fungus attack. The variety Valencia appeared most susceptible, while Virginia Runner, African, and V. subterranea were found practically immune to S. rolfsii. Investigations have shown that the fungus retains its vitality in the soil for at least three years, and as a consequence the planting of resistant varieties is recommended rather than attempting to rid the soil of the pest by rotation.

In connection with the growing of peanuts, crimson clover is said to be commonly used as a winter cover crop. This plant did not suffer attack by *S. rolfsii* so far as observations during the seasons of 1915 and 1916 showed.

The Verticillium disease of the potato, G. H. Pethybridge (Sci. Proc. Roy. Dublin Soc., n. ser., 15 (1916), No. 7, pp. 63-92. pls. 2; abs. in Roy. Bot. Gard. Kew. Bul. Misc. Inform., No. 4 (1916), pp. 110-112).—Reporting a more prolonged and more detailed study of the Verticillium disease than the one previously noted (E. S. R., 34, p. 443), the author describes the general symptoms as those of a process of gradual desiccation, resulting in the more or less premature death of the plant. The mycelium of V. albo-atrum is found in the wood vessels of all parts of affected plants, passing into the corresponding vessels of growing tubers and thence into the young plants arising from such

tubers when used for seed. The disease is not strictly localized at or near the heel end of the tuber, as formerly supposed. The fungus grows well as a saprophyte. The disease is reproduced on infecting sound plants with pure cultures. It is considered advisable to remove this disease from the category of those usually designated by such terms as leaf roll and curl, since the Verticillium disease is regarded as a specific type of those in which the mycelium affects the wood vessels and for which the term hadromycosis is suggested.

The disease does not appear to be very common or destructive in the British Isles at present. Preventive measures include rotation and use of seed known to be free from infection.

Potato spraying experiments for the control of early blight (Alternaria solani), R. W. Jack (Rhodesia Agr. Jour., 10 (1913), No. 6, pp. 852-862, pl. 1).—A preliminary account is given of the methods and results of spraying tests for control of early blight, the only leaf disease of potatoes prevalent in this territory at the time of the report.

The author states that the disease may be treated profitably with a 4½:4½:50 Bordeaux mixture, if commenced when the plants are from 4 to 6 in high (but not when the disease has become apparent on the leaves), three or four sprayings giving good results, but seven weekly sprayings being preferable. Not less than 75 gal. per acre should be employed. Knapsack pumps with copper tanks have been found suitable to local conditions. An arsenical may be added for insects if desired.

Does it pay to spray potatoes in southern Rhodesia? R. W. Jack (Rhodesia Agr. Jour., 13 (1916), No. 3, pp. 354-360, pls. 2).—In a progress report of work continued for three years following that above noted, it is stated that Alternaria solani, while not usually severe on early crops grown on irrigated ground, causes losses sometimes amounting to 50 per cent on ground depending on rainfall alone if not properly sprayed. The work herein reported, which dealt with the fairly resistant variety Up-to-Date, is said to show that the employment of a 4:4:40 Bordeaux mixture, begun early and repeated weekly, is profitable to growers in localities where the disease is prevalent.

Weather injury to rice in 1915 in Italy, B. Marcarelli (Gior. Risicolt., 5 (1915), No. 13, pp. 212-216, fig. 1; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 9, p. 1253).—A period of cool, moist weather from May 27 to June 4, 1915, was associated with an unusually severe chlorosis, sometimes death of the foliage, of rice plants and weakness of the stalk, these conditions being only in part relieved by the return of more favorable weather. Puccinia oryzæ, though found on the foliage in numerous cases, was regarded as only secondary in its attack, which was supposedly induced by the condition of lowered vitality in the rice plants.

Fusarium blight, or wilt disease, of the soy bean, R. O. CBOMWELL (U. S. Dept. Agr., Jour. Agr. Research, 8 (1917), No. 11, pp. <math>421-440, pl. 1, fig. 1).— In a contribution from the North Carolina Experiment Station, the author describes a disease of soy beans due to F. tracheiphilum and gives the results of investigations to determine the parasitism of this species of Fusarium and the relationship of the species on the soy bean to that causing a wilt disease of cowpens.

The disease on the soy bean is characterized by a chlorosis and shedding of the leaves or leaflets, followed by the death of the plants. It has been observed in several localities in North Carolina on soils infected with cowpea wilt. Cultural and morphological studies, as well as reciprocal inoculation experiments, have shown that the two diseases are caused by the same species of Fusarium. Infection is thought to occur through the roots, but the presence of nematodes does not appear to increase the percentage of blight. The character of the soil

is considered to influence the amount of infection, the largest proportion of diseased plants occurring on coarse, sandy soils.

Black rot of tobacco, K. PREISSECKER (Fachl. Mitt. Österr. Tabakregie, 15 (1915), No. 4, pp. 113-116, figs. 4).—This is a brief discussion of the disease attacking stored tobacco due to Sterigmatocystis nigra (Aspergillus niger). The accounts given by Rapaics (E. S. R., 30, p. 450) and others are referred to.

Suggestions for the control of the more serious plant diseases occurring at Hood River, L. Childs (Oregon Sta. Bul. 141 (1917), pp. 28-32).—Based upon experiments carried on in this region, directions are given for the spraying of apple, pear, and peach trees for the control of the more important diseases to which they are subject.

Diseases of the apple, pear, and quince, C. R. Orton (*Proc. State Hort. Assoc. Penn.*, 57 (1916), pp. 45-52, pls. 4).—The author has limited the discussion in this paper to diseases of orchard fruits not treated in the communication previously noted (E. S. R., 35, p. 351). The several diseases are dealt with alphabetically in connection with their hosts.

The oak fungus disease of fruit trees, W. T. HORNE (Proc. Fruit Growers' Conv. Cal., 47 (1915), pp. 208-215).—This includes a report on experiences with, also a discussion of, the oak fungus and wood decay of fruit trees.

It is stated that English walnut budded about a foot above the ground on California black walnut is safe from the oak fungus. Isolation trenches, if kept open and disinfected, are successful in checking the spread of the infection by means of rhizomorphs. The fungus goes down several feet. The effects of carbon bisulphid in the soil are variously reported, depending apparently on soil conditions.

Wood decay of fruit trees appears to be more widely destructive in this region than the oak fungus, as it affects wild growths abundantly. Unlike the oak fungus, it can not enter except through a break made in the bark. The fruiting bodies, after being dry all the summer, may give off infecting spores within 24 hours after being moistened. The fungus works in the wood chiefly or exclusively. Wounds should be painted before being wet, and they should be kept covered with paint or other reliable disinfectants, among which corrosive sublimate is considered to be one of the best. It is thought that apples and walnuts, carefully protected from disease, may live 100 years.

Observations on the relation of the height of fruit to apple scab infection, L. Child (Oregon Sta. Bul. 141 (1917), pp. 5-17, flgs. 6).—While engaged in some experiments on apple scab, the author observed that the fruits near the top of the trees were usually much more scabby than those produced nearer the ground. In following up this observation, several orchards were examined as to the actual conditions existing at harvest in certain trees that had been carefully sprayed.

It was found that at least one-fourth of the crop in case of most of the trees was produced at a height of 15 ft. or more, and at least one-half of this amount was found to be scabby, while lower and poorer quality fruit possessed a very slight scab infection. On smaller trees sprayed in exactly the same manner as the above, much better results were obtained. Under the conditions prevailing in the Hood River region during the spraying season, the average wind velocity is said to be too great for good spraying at a height of more than 22 or 23 ft. On this account, it is recommended that a tower be used in spraying and that long, out-of-the-way limbs be cut back.

Blister canker control, H. E. Vasey (Nebr. Hort., 6 (1916), No. 7, pp. 1-3).—Stating that apple blister canker is to be found in fully 96 or 97 per cent of the orchards in Nebraska, the author discusses practical means of control. These include acquaintance with the disease, skillful scraping and pruning

of the cankered limbs, disinfecting and covering of wounds, and careful observation of all trees for at least two years after the completion of the above treatment.

[Notes on some plant diseases] (New Mexico Sta. Rpt. 1916, pp. 25, 26).—In continuation of investigations on the chlorosis of pear trees (E. S. R., 32, p. 641), it is stated that trees treated with ferrous sulphate in 1914-15 showed some benefit from plugging the salt in holes bored in the trees. Where young pear trees were sprayed in 1915 with a 1 per cent solution of ferrous sulphate, they continued to show in 1916 the same yellow color exhibited in the previous year.

It is stated that pear blight was more serious in 1915 than in any season previously noted.

Diseases of the brambles and methods of controlling them, C. R. Obton (Proc. State Hort. Assoc. Penn., 57 (1916), pp. 66-71, pls. 3).—This is a discussion of various diseases of blackberry, raspberry, and dewberry, with recommendations regarding measures for their control.

Direct bearer grapevines in relation to disease, G. Dalmasso and S. Sutto (Rivista [Concgliano], 5. scr., 21 (1915), No. 15, pp. 337-341; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 9, pp. 1257-1259).—Examination of direct bearer vines in July, 1915, at the Royal College of Enology at Conegliano showed that in spite of the unfavorable season none of the vines were attacked by Peronospora or by Oldium. Some showed melanose (Septoria ampelina), some anthraenose (Glæosporium ampelophagum). A number of varieties are reported upon in detail as regards the presence or absence of the several diseases under observation, a gratifying degree of resistance being apparent in most instances.

The pink disease of cacao, J. B. Rober (Bul. Dept. Agr. Trinidad and Tobago, 15 (1916), No. 3, pp. 86-89, pl. 1).—From reports of studies or observations in several parts of the world, the conclusion is reached that the pink disease, whether in the East or in the West, is caused by the same fungus, Corticium salmonicolor. The disease as it occurs in very characteristic form on cacao is described. In the East, the fungus has been found on 141 different species of plants.

Careful removal of all affected portions is said to be effective where its occurrence is sporadic. In case of old trees or where many are affected, good results are obtained by treating with tar on the first appearance of the symptoms in each case.

Tea roots, A. C. Tunstall (Indian Tea Assoc. [Pamphlet] 1 (1916), pp. 22, pls. 5, figs. 11).—This pamphlet discusses first the characters and behavior of healthy tea roots and, second, some root diseases, their transmission, their identification, and general plans for their treatment. The disease fungi mentioned include Diplodia, Rosellinia, Hymenochate noxia, Fomes lucidus, Ustulina zonata, and Thyridaria tarda.

Ustulina zonata, a fungus affecting Hevea brasiliensis, A. Sharples (Dept. Agr. Fed. Malay States Bul. 25 (1916), pp. 27, pls. 10).—It is stated that during the past two years the fungus U. zonata has become an important factor in the Federated Malay States. It is the cause of a collar and root disease which develops typically in rubber trees over 10 years of age but has been found in trees aged from 5 to 8 years. The trouble was noted by the author in 1913, but evidence recently obtained suggests that it has been present in this region for several years, perhaps since 1907. The typical dry rot produced by U. zonata is said to be unmistakable, the wood in advanced cases crumbling readily on slight pressure. Control measures consist in thoroughly cleaning out the portions of the tree that have been cut away during the

process of clearing and thinning and in such sanitation measures as giving early attention to wounds arising from different causes.

Cryptogamic diseases of forest trees, P. Guinier (Vie Agr. et Rurale, 6 (1916), No. 45, pp. 334-338, figs. 6).—Briefly discussing types of fungus tree diseases, circumstances favoring their development, and measures for their control in forest areas, some of which are said to show deterioration as regards both the quantity and the quality of growth produced, the author holds that remedial measures, to be practically preventive, must look to the prevention of disease by the improvement of living conditions for the trees.

## ECONOMIC ZOOLOGY-ENTOMOLOGY.

Bird friends.—A complete bird book for Americans, G. H. Trafton (Boston: Houghton Mifflin Co., 1916, pp. XVIII+330, pls. 30, figs. 7).—A popular work relating to the value of birds, their enemies, attraction and protection, and study in schools.

How to make friends with birds, N. M. Ladd (Garden City, N. Y.: Doubleday, Page & Co., 1916, pp. 10-228, figs. 165).—A small pocket guide.

The birds of Britain: Their distribution and habits, A. H. Evans (London: Cambridge University Press, 1916, pp. XII+275, figs. 94).—A short handbook which includes the results of the most recent observations of British birds.

The zoological position of the Sarcosporidia, H. Crawley (Proc. Acad. Nat. Sci. Phila., 68 (1916), pt. 3, pp. 379-388).

Microtechnical methods for studying certain plant-sucking insects in situ, K. B. Brown (Science, n. ser., 44 (1916), No. 1143, pp. 758, 759).—The author describes methods which he has made use of for determining the relation of certain sucking insects to their host plants.

Studies on gregarines, MINNIE E. WATSON (Ill. Bvol. Monographs, 2 (1916), No. 3, pp. 258, pls. 15).—This work includes descriptions of 21 new species and a synopsis of the eugregarine records from the Myriapoda, Coleoptera, and Orthoptera of the world.

[Cranberry insects], H. J. Franklin (Ann. Rpt. Cape Cod Cranberry Growers' Assoc., 28 (1915), pp. 19-31).—Substantially noted from another source (E. S. R., 36, p. 54).

The rôle of insects as carriers of fire blight, H. A. Gossard (Ohio State Hort. Soc. Ann. Rpt., 49 (1916), pp. 73-83).—The observations here reported, relating to the honeybee, have been largely noted (E. S. R., 35, p. 662).

Summary of the season's experiments with the newer insecticides, J. S. Houser (Ohio State Hort. Soc. Ann. Rpt., 49 (1916), pp. 49-56).—A summary of the work at the Ohio Experiment Station from which the author concludes that the home-boiled, dilute lime-sulphur wash, the commercial concentrated lime-sulphur wash (1:7), and the soluble oils (usually 1:15) are standard remedies for the San José scale and will control it if properly applied. The soluble oils, used at the strength of 1:15, controlled the elm bark louse, the elm Aspidiotus, the tulip tree lecanium, the pit-making oak scale, the scurfy scale of the honey locust, the Putnam scale, the oak kermes, and the obscure scale.

Analyses of some more recent and older pest remedies, M. R. MILLER (Mo. Bul. Com. Hort. Cal., 6 (1917), No. 1, pp. 23-26).—This paper reports upon analyses made of newer remedies and of those in regard to which there appears to be doubt as to their composition.

Fly poisons.—Studies on sodium salicylate, a new muscicide, and on the use of formaldehyde, E. B. Phelps and A. F. Stevenson (Pub. Health Rpts. [U. S.], 31 (1916), No. 44, pp. 3033-3035).—The authors find that a 1 per cent

solution of sodium salicylate is slightly less efficient than formaldehyde, but that it possesses certain marked advantages, especially for household use. The best results with formaldehyde were obtained from a solution containing 1 per cent of the formaldehyde, or 2.5 per cent of the 40 per cent solution.

Suggestions for the control of the more serious insect pests occurring at Hood River, L. Childs (*Oregon Sta. Bul. 141 (1917*), pp. 33, 34).—These notes relate to the leaf-roller, brown aphis, woolly apple aphis, green apple aphis, codling moth, pear leaf blister mite, and San José scale.

[Report of the] division of zoology and entomology (Washington Sta. Bul. 136 (1917), pp. 35-42, figs. 8).—Brief reference is made to the occurrence of and work with the coulee cricket (Peranabrus scabricollis), noted below.

Work with the strawberry root weevil (Otiorhynchus ovatus) has been carried on under a special appropriation made by the commissioners of Benton County, where it has appeared in the Kennewick region and rendered acres of berry fields worthless. In the course of the work, which was based principally on soil fumigation, numerous materials were tested. Carbon disulphid is the only material that has given promise of practical value, and this only when applied under a cover, such as oil cloth, canvas, etc.

Brief reference is made to the continuation of work on progressive immunity of insects, an account of which has been previously noted (E. S. R., 34, p. 551). A discussion of the physiological effects of endoparasitism in aphids is also included.

Annual report on the entomological laboratory for the year ended March 31, 1914, T. J. Anderson (Dept. Agr. Brit. East Africa Ann. Rpt. 1913-14, pp. 52-83).—This is the report of the work of the year with the more important insects, particularly with the coconut beetle (Oryctes monoceros).

List of Egyptian insects in the collection of the Ministry of Agriculture, G. Store (Min. Agr. Egypt, Tech. and Sci. Serv. Bul. 5 (1916), pp. V+50).—Of the 154 families represented in the list here presented about 100 are said to include species of economic interest.

The fauna of British India, including Ceylon and Burma, edited by A. E. Shipley and G. A. K. Marshall (London: Taylor & Francis, 1916, vol. 6, pp VIII+248, figs. 177).—This volume of the work previously noted (E. S. R., 25, p. 557), is an appendix to the Homoptera, by W. L. Distant, and describes 348 species of which many are new.

The coulee cricket [Peranabrus scabricollis], A. L. Melander and M. A. Yothers (Washington Sta. Bul. 137 (1917), pp. 56. figs. 37).—The first part of this bulletin (pp. 5-35), by A. L. Melander, consists of a general discussion and photographs; the second part (pp. 36-50), by M. A. Yothers, consists of miscellaneous notes on the biology of the coulee cricket (P. scabricollis), a brief account relating to the control of which has been previously noted (E. S. R., 35, p. 756).

This cricket has been a source of injury in Washington State since 1899, when outbreaks were first observed by C. V. Piper. It occurs sporadically in restricted localities in the Big Bend country of central Washington, where immense migratory hordes destroy whatever vegetation grows in their pathway. It breeds in nonarable areas characterized by the presence of scabland sage brush (Artemisia rigida), among the fallen leaves of which the newly hatched crickets secure protection in early spring. During the first four of its seven stages the cricket feeds in the breeding grounds and at the fifth instar it begins moving in bands and spreads over miles of country. The eggs are deposited singly during the migration whenever the insects come to a favorable location, usually at the base of grass stems, each female averaging about 50 eggs. This cricket

is practically omnivorous. It is marked cannabalistic, attacking and devouring weakened individuals throughout its life cycle.

The parasite Sparaison pilosum has been reared from its egg and Calosoma zimmermanni, Cyrtopoyon maculosis, and species of ants have been observed as predatory on small crickets. The crickets are more easily reached and killed when young before they have spread from the restricted breeding grounds. At this time spraying with a 5 to 10 per cent kerosene emulsion, the use of fresh horse manure containing 2 per cent of an arsenical as a poisoned bait, and burning with straw or with an insecticidal blast torch are practical. Migratory crickets may be checked by vertical walled ditches containing deeper pitfalls dug across their path, since through massing in the pits, they quickly smother out each other's lives. Fencing of 1 by 8 in. boards joined end to end on edge and furnished with frequent pitfalls is sometimes employed in place of ditching.

Results of work against the locust in Uruguay, R. Sundberg et al. (Defensa Agr. [Uruguay] Mem., 1915, pp. 154, figs. 19).—A report upon locust control work in 1914–15.

The pear thrips in British Columbia and its control, A. E. CAMERON and R. C. TREHERNE (Agr. Gaz. Canada, 3 (1916), No. 11, pp. 946-952, figs. 4).— This paper reports upon observations of this pest in British Columbia, where it was first discovered in April, 1915, as recorded by Hewitt. It has been found in that Province throughout the district lying between Victoria and Sidney in the Saanich Peninsula, being more or less uniformly distributed within this area. It has also been found at Duncan and is thought to occur at Nanaima. Quite satisfactory results were obtained from spraying.

The tomato and bean bug (Nezara viridula), W. W. Froggatt (Agr. Gaz. N. S. Wales, 27 (1916), No. 9, pp. 649, 650, pl. 1).—This bug, which first appeared on tomato plants in the neighborhood of Sydney some five years ago, has increased in numbers during the last two years and become a pest of the fruits and foliage of the tomato, the foliage and young pods of French beans and potato plants.

The Helopeltis question, especially in connection with cacao, W. ROEPKE (Meded. Proefstat. Midden-Java, No. 21 (1916), pp. 40+III; abs. in Rev. Appl. Ent., Ser. A, 4 (1916), No. 11, pp. 442-444).—A discussion of Helopeltis antonii and H. theivora, including their economic status, biology, natural enemies, and control measures.

The maple aphis and its dimorphic larva, E. J. BUNNETT (*Proc. So. London Ent. and Nat. Hist. Soc.*, 1915-16, pp. 21-24, pl. 1).—Reports observations of the biology and anatomy of *Chaitophorus aceris*.

Scale insects and their control, R. T. Cotton (Porto Rico Bd. Agr. Expt. Sta. Circ. 9 (1917), pp. 7; Spanish Ed., pp. 7).—A brief popular account.

Mimicry in butterflies, R. C. Punnett (London: Cambridge University Press, 1915, pp. VIII+188, pls. 16, figs. 8).—A popular work.

The bollworm in Egypt, G. C. Dudgeon (*Trans. 3. Internat. Cong. Trop. Agr. 1914, vol. 1, pp. 399-432, pls. 2*).—This extended account of the biology, economic status, natural enemies, and control measures for the Egyptian bollworm (*Earias insulana*) includes much data relating to its immature stages taken from a contribution by F. C. Willcocks published in 1905. See also another note (E. S. R., 30, p. 252). A colored plate of the several forms of the adult after Storey (E. S. R., 32, p. 152) is included.

Control of the gipsy moth by forest management (U. S. Dept. Agr. Bul. 484 (1917), pp. 54, pl. 1).—This bulletin consists of two parts.

<sup>&</sup>lt;sup>1</sup> Agr. Gaz. Canada, 2 (1915), No. 8, pp. 734-737.

<sup>&</sup>lt;sup>2</sup> Yearbook Khediv. Agr. Soc., Cairo, 1905, pp. 57-91.

I. The gipsy moth in woods, by G. E. Clement (pp. 1-16).—The subject is dealt with under the headings of behavior of the gipsy moth in the woods, composition and condition of woods in infested territory, feeding habits of gipsy moth caterpillars, precautions needed, application of food plant data to individual species, other measures in need of attention, and recommendations. A plan of procedure for woodland owners who wish to improve and protect their woods is suggested.

II. Management of typical woodlots infested with the gipsy moth in the white pine region, by W. Munro (pp. 17-54).—In this second paper an attempt is made to coordinate the results of food plant experiments with known principles of forest management and with economic conditions in the infested region with a view to determining the extent to which forest management may be relied upon in the control of the moth. The subject is dealt with under the headings of susceptibility to gipsy moth attack as a basis of management, other factors in management for moth control, some controlling factors in management, trees which control, typical stands, and conclusions.

Each lot and each combination of species presents a problem in which the controlling factors are site, soil, location, market, species present, their value and relative proportion, the degree of infestation, and the cost of labor.

A map of the forest regions of New England showing their relation to the region infested by the gipsy moth, July 1, 1916, is attached.

Further observations on the control of the fruit tree leaf roller in the Hood River Valley, L. Childs (Oregon Sta. Bul. 141 (1917), pp. 18-27).—In further work with this insect (Archips argyrospila) (E. S. R., 34, p. 552; 35, p. 551), it was found that fair, settled weather for several days following spraying is the most important factor in the destruction of its eggs. A continued rainfall for four days following spraying was found to destroy the effectiveness of the miscible oil. Emulsions made from eastern or paraffin-base oils spread better than the western or asphaltum-base oils. The addition of 1 to 2 gal. of liquid soap to 100 gal. of emulsion greatly increased the spreading properties of the spray. "Oil sprays do not 'set' with the rapidity of other applications used in the apple orchard. Oil which could be removed by rains has been found on the trees as long as a week after application—it must be considered active while in this form. The other orchard sprays set within two to eight hours and effectiveness from that time on is only slightly reduced by continued rains."

In trapping work, as many as 600 leaf roller moths were caught during a single night by a Tungsten electric light trap. Of these 95 per cent were males, 3 per cent spent females, and 2 per cent female moths containing eggs.

"Miscible oils used at the rate of 6:100 during 1915 and 1916, though causing considerable foliage injury when used after the fruit buds begin to show, have not injured these buds in numbers sufficient to reduce the crop or to cause any injury to the tree other than slightly retarding its development. In both years a very high percentage of the eggs was destroyed when the oils were applied at this time. Oils applied late can usually be applied during a period of warm settled weather."

A new method of controlling the black-head fireworm, H. B. SCAMMELL (Proc. Amer. Cranberry Growers' Assoc., 47 (1916), pp. 8-12).—In the control of Rhopobota vacciniana the author recommends that the winter flowage be withdrawn about May 10 in an effort to bunch the hatching of the fireworm eggs. Nicotin sulphate should be applied at the rate of 200 gal. of spray per acre at each application, the first application to be made about May 20, followed in five days by a second application. Where there is more than a scattering of the second brood worms, a third application should be made when the majority

of the eggs have hatched, or about the end of the first week in July. The following formula to make 200 gal. of the 40 per cent nicotin sulphate spray is recommended: Dissolve 8 lbs. of fish-oil soap in a small amount of water, add the dissolved soap to nearly the required amount of water in the spray tank, and then add 1 qt. of nicotin sulphate diluted with the remainder of the water.

Life cycle of Tortrix viridana, A. Sich (*Proc. So. London Ent. and Nat. Hist. Soc.*, 1915-16, pp. 15-20).—The studies here reported relate to a leaf roller enemy of the oak in England.

[Codling moth investigations] (New Mexico Sta. Rpt. 1916, pp. 31-34).—This is a brief report of results of observations of the life history and habits of this pest in New Mexico, together with codling moth spraying schedules for 1916.

Spraying for codling moth, C. C. VINCENT, W. C. EDMUNDSON, G. J. DOWNING, and E. P. Taylor (*Idaho Sta. Bul. 92 (1916*), pp. 25-27).—This is a brief report of progress on spraying work with the codling moth commenced three years ago with a view to determining the relative efficiency of one, two, and three applications of arsenate of lead and for the purpose of comparing the efficiency in the control of the codling moth of two well-known brands of powdered arsenate of lead. The results obtained from spraying for three years are reported in tabular form. It is believed that either brand of material properly applied will prove satisfactory.

"The first or calyx spray should be applied when from 80 to 90 per cent of the petals have fallen, or work should begin in time to complete the first spray before the calyx lobes have closed. . . . The second spray should be applied about three weeks after the first. . . . To determine the time for the application of a third spray the trees should be banded about the middle of June. The spray should be given 20 days after the first larvæ come down under the bands. Trap or breeding cages may also be employed to determine the exact time for the application of the third spray. It should be applied when the first moths appear.

"The number of applications will depend on the infestation the previous year, the variety of the fruit, the infestation in neighboring orchards, effectiveness of early sprays, and seasonal conditions. The early calyx spray, however, is the most important. If this and other early brood sprays are neglected or improperly applied when the worms are bad, no amount of spraying late in the season will save the crop."

Life history of some Japanese Lepidoptera containing new genera and species, K. Nagano (Bul. Nawa Ent. Lab. [Japan] No. 1 (1916), pp. 27+[102], pls. 9).—This bulletin gives descriptions of the immature stages of 31 species of Lepidoptera, together with colored illustrations of the larvæ and drawings illustrating the structure of the several stages. Three genera are erected and one species and one variety described as new to science.

District of Columbia Diptera: Syrphidæ, N. Banks, C. T. Greene, W. L. McAtee, and R. C. Shannon (*Proc. Biol. Soc. Wash.*, 29 (1916), pp. 173-203).—One hundred and thirty-six species and two varieties are recorded from the District of Columbia.

The relation of malaria to crop production, D. L. VAN DINE (Sci. Mo., 3 (1916), No. 5, pp. 431-439, figs. 2).—This paper is based upon investigations conducted since 1913 by the Bureau of Entomology of the U. S. Department of Agriculture in the South, particularly in Madison Parish, La., a report of which work has been previously noted (E. S. R., 33, p. 255), together with data obtained from the Office of Farm Management of the Department.

Mosquitoes and man again, C. S. Ludlow (Science, n. ser., 44 (1916), No. 1144, pp. 788-790).—A continuation of the discussion previously noted (E. S. R., 36, p. 552).

On Delphastus catalinæ, a valuable ladybird enemy of the white flies. H. S. SMITH and E. J. Branigan (Mo. Bul. Com. Hort. Cal., 5 (1916), No. 12, pp. 448-450, flgs. 4).—D. catalinæ, which was first observed during the summer of 1915 feeding upon a heavy infestation of Aleyrodes kelloggi on Catalina cherry at Pasadena, Cal., has been found to be largely confined in its food habits to white flies. The species has since been introduced into Florida, where it is thought that it will prove of considerable value.

Two destructive grape insects of the Appalachian region, F. E. BROOKS (Off. Rpt. Sess. Internat. Cong. Vit., 1915, pp. 237-248, figs. 10).—This paper relates to the grape curculio and the grape root borer, accounts of which by the author have been previously noted (E. S. R., 18, p. 61; 19, p. 962).

It is stated that the grape curculio is the most destructive insect attacking the fruit of the grape in many parts of the Appalachian region and also in some sections of the Mississippi Valley, causing in some localities a loss of 100 per cent of the crop on unprotected vines. The species is also recorded as occurring in destructive numbers in certain parts of Kentucky, Ohio, Illinois, Missouri, and Arkansas. The grape root borer is said to be especially destructive in certain localities in the Appalachian region, the most severe injury to grapevines having been reported from West Virginia and Kentucky.

Life history and feeding records of a series of California Coccinellidæ, C. P. CLAUSEN (Univ. Cal. Pubs., Ent., 1 (1916), No. 6, pp. 251-299).—The studies here presented were conducted during the spring and summer of 1918 at Sacramento and during 1914 at Berkeley and Riverside.

"The life history of an aphid-feeding coccinellid under normal summer conditions in California, based upon the results secured from eight species, may be given as 27 days, divided as follows: Egg stage, 5 days; first larval stage, 5 days; second, 3 days; third, 3 days; fourth, 6 days; and the pupal stage, 5 days.

"The number of aphids eaten by the larvæ of the different species is in proportion to the size of the individuals. The above, to a limited extent, may be said to be true in the case of the adults also. Temperature and humidity are very strong contributing factors in the development and behavior of the various species.

"The number of eggs to be expected under normal field conditions will vary from 200 to 500, or occasionally more, and extending over a period of from 4 to 8 weeks where the female has lived the full adult life under optimum conditions. The period intervening between emergence and mating is 1 to 3 days, and from mating to oviposition, 8 to 11 days, thus giving a period of from 10 to 15 days after emergence before oviposition may be expected. Oviposition normally takes place daily, with occasional exceptions. Only one fertilization is necessary during the life of the female, fertile eggs having been produced in one instance 55 days after mating."

Studies of weevils (Rhynchophora) with descriptions of new genera and species, W. D. Pierce (Proc. U. S. Nat. Mus., 51 (1916), pp. 461-473, figs. 2).— The author erects three new families, five new subfamilies, one new tribe, and one new genus, and describes two new species, namely, Leiomerus granicollis from specimens found alive in cassava stems from Brazil at Washington, D. C.; and Eisonyx (Eumononycha) picipes from a specimen collected in a strawberry field at Nashville, Tenn. The latter has also been collected at Nashville from aster roots.

Nosema apis in Victoria, F. R. BEUHNE (Jour. Dept. Agr. Victoria, 14 (1916), No. 10, pp. 629-632).—Though widely distributed in Australia N. apis appears to be merely an occasional inhabitant of the alimentary canal of the

bee. Losses are said to occur only after seasons of drought and no fresh outbreaks of the disease follow the restocking with bees of defunct hives.

Spore-forming bacteria of the apiary, A. H. McCray (U. S. Dept. Agr., Jour. Agr. Research, 8 (1917), No. 11, pp. 399-420, pls. 2, figs. 6).—The first part of this paper consists of descriptions and comparisons of Bacillus mesentericus, B. vulgatus, and B. orpheus, three of the five spore-bearing species occurring commonly about the apiary, B. alvei and B. larvæ having previously been considered by White (E. S. R., 18, p. 561). Reference is first made to the statement of Lambotte in 1902 that foul brood of bees can be produced by feeding them cultures of B. mesentericus vulgatus grown upon a special medium prepared from the juices of bee larvæ, and also that by the use of this special medium B. alvei arises as a special variety of the above-mentioned bacillus and produces, on feeding, tissue changes characteristic of the disease (E. S. R., 14, p. 678).

The second part of the paper consists of a report on inoculation experiments. The author finds that mistakes in the identification of these spore-forming bacteria might well be made, especially without knowledge of their occurrence, and that many of the earlier investigators of bee diseases confused these species. The author's studies of *B. vulgatus*, *B. mesentericus*, and *B. alvei* led him to conclude that the biological differences of the three species are too great to warrant expecting the transformation from one to another in any short period of time. "Even if it is granted that Lambotte fed pure cultures of *B. alvei*, his results would not agree with those of present-day investigators of bee diseases, since *B. alvei* has not been found to produce disease in bees upon repeated inoculations."

A list of 19 references to the literature is included.

Some weather-proof bands for use against ants, J. R. Hobton (Mo. Bul. Com. Hort. Cal., 5 (1916), No. 11, pp. 419-421).—This paper describes the best formulas for banding mixtures that were developed in the course of a series of experiments in which some 20 combinations were tested.

A mixture consisting of corrosive sublimate, which has a repellent and toxic action, and commercial tree-sticky, at the rate 1:6, has been found to give the best consistency, no ants crossing and no spreading or renewal being needed for a period of three months. The softness of the mercuric tree-sticky band was equally well maintained by substituting flowers of sulphur for the mercury salt.

New Javanese chalcidoid Hymenoptera, A. A. GIBAULT (*Proc. U. S. Nat. Mus.*, 51 (1916), pp. 479-485).—Two genera, ten species, and one variety are here described as new to science, among which are *Cheiloneuromyia javensis*, Cristatithorax latiscapus, Coccophagus javæ, Asemantoideus dubius, Epitetrastichus lecanii, and Epitrastichus ibseni, all reared from the green scale at Salatiga, Java.

Some chalcidoid parasites of the seeds of Myrtaceæ, A. da Costa Lima (Arch. Mus. Nac. Rio de Janeiro, 19 (1916), pp. 193-203, pls. 2).—This paper includes descriptions of three seed chalcids that attack guava (Psidium spp.) in Brazil, namely, Syntomaspis myrtacearum n. sp. Prodecatoma sp., and Eurytoma sp.

Observations on the insect parasites of some Coccidæ.—I, On Aphelinus mytilaspidis, a chalcid parasite of the mussel scale (Lepidosaphes ulmi), A. D. IMMS (Quart. Jour. Micros. Sci. [London], n. ser., 61 (1916), No. 243, pp. 217-274, pls. 2, figs. 5).—This paper deals at length with the life history, bionomics, and economic status of A. mytilaspidis, a parasite of the oyster-shell scale (L. ulmi) as observed in England.

There are two generations a year, parthenogenesis apparently being the usual method of reproduction. The adults of the first generation appear in greatest frequency between the third week in June and the middle of July, and of the second generation between the middle of August and the first week in September. The efficiency of this parasite is said to be far below that of the most effective insecticides, due primarily to four factors, namely, its extremely limited powers of migration, its relatively low fecundity, its marked susceptibility to the influence of unfavorable climatic conditions, and the effects of the second annual generation of parasitism being only partial and incomplete.

A list of 33 references to the literature is included.

## FOODS-HUMAN NUTRITION.

The use of cotton seed as food, T. B. Osborne and L. B. Mendel (Jour. Biol. Chem., 29 (1917), No. 2, pp. 289-317, figs. 5).—This paper reports data compiled from experiments with laboratory animals (rats) which were fed cotton-seed products of various descriptions. The following facts were established as results of these experiments:

Cottonseed kernels were found to be unsatisfactory for nutrition. All of the animals receiving this product in the ration died within two weeks. The samples of cottonseed meal and flour tested were found to be valuable foods for growing rats, both when used as a sole source of protein in the diet and when used in smaller quantity to supplement their less efficient protein concentrates.

The injurious substances in the kernels can be removed by extraction with ether and, according to other investigators, by extraction with carbon bisulphid, chloroform, benzene, or alcohol, but not with petroleum ether or gasoline. The ether-soluble material is deleterious, either because it contains some toxic ingredients or else because it renders the food so unpalatable that the animals refuse to eat it. Foods containing cottonseed oil prepared by cold pressing or the crude unbleached commercial oil prepared by hot pressing were eaten without detriment by the rats.

"By treatment with steam under suitable conditions the kernels lose their deleterious effect on rats. The variations in the results of feeding different samples of cottonseed meal, which have been reported, may be due to differences in the mode of heating which the products have experienced in their preparation."

With regard to the question as to whether cottonseed injury in the feeding of domestic animals can be classed with the deficiency diseases, the authors state that it is possible that food mixtures lacking some of the now recognized essential ingredients of an adequate diet have been employed in the past. Experiments with rats which were grown successfully on cottonseed rations excluded the probability that there is ordinarily any lack of the water-soluble vitamin. There is no definite information that the quota of inorganic salts furnished in agricultural products is always sufficient.

The authors have "induced young rats to double their weight at a normal rate of growth on a food mixture containing nothing except cottonseed meal, starch, and lard. The deleterious effects of unheated cottonseed kernels can not be denied. Whether the reputed detrimental effect after feeding some of the commercial cottonseed meals is associated with a failure to destroy a deleterious constituent—as has been indicated above—or is attributable to unsuitable methods of feeding in some cases is still debatable. The treatment of the cotton seed so as at least to render it harmless now seems to lie within the range of ready possibilities."

The nature of the dietary deficiencies of the oat kernel, E. V. McCollum, N. Simmonds, and W. Pitz (Jour. Biol. Chem., 29 (1917), No. 2, pp. 341-354, figs. 9).—This paper reports data obtained in feeding experiments with laboratory animals regarding the supplementary relations between the oat kernel and isolated food factors. The results of these experiments may be summarized briefly as follows:

The proteins of the oat kernel seem to be of poorer quality than those of the maize or wheat kernel. With all other dietary factors properly adjusted, 9 per cent of oat protein served to induce a small amount of growth at the beginning of the experiments, but cessation of growth followed after about one month and thereafter the animal remained stationary in weight or declined. Casein does not appear to supplement the proteins of the oat kernel satisfactorily and the addition of this to oat proteins does not induce growth at the maximum rate, as does the combination of casein with wheat protein or with maize protein. Combinations of gelatin and oat proteins in about equal proportions proved to be superior to casein and oat protein combinations.

"The unidentified dietary factor fat-soluble A is present in very small amount in the oat kernel. It is not possible to supplement the oat kernel with inorganic salts and purified protein so as to induce growth beyond the third month. The inclusion of butter fat or some other substance which supplies the unknown A prevents the failure at this point, just as it does in experiments where the ration consists of purified protein, salts, carbohydrates, and an extract which furnishes the dietary factor B.

"The whole oat kernel, with the hulls removed in the laboratory by coarse grinding and fanning, will not induce any growth in young rats. A mixture of hulled oats or rolled oats with 5 per cent of butter fat induces very slow increase in body weight for at least 125 days.

"The oat kernel, like unpolished rice, wheat, wheat germ, maize kernel, alfalfa leaves, cabbage, and clover leaves, contains a liberal supply of the water-soluble B, the preparations of which induce relief from polyneuritis. . . .

"The addition of any single dietary component as protein, inorganic salts, or fat-soluble A does not supplement the oat kernel so as to induce appreciable growth. The addition of two dietary factors to the oat kernel serves to induce good growth during the first 60 days when one of the additions is a suitable salt mixture. Without modifying the inorganic content of the ration when this is derived solely from the oat kernel . . . rats have not made any marked increase in body weight. When the oat kernel is fed supplemented by but two dietary factors there is always early failure with loss of weight and death following the brief period of growth. . . .

"The oat kernel, like the wheat kernel, appears to cause injury to the animals when their diet is of such a character as to lower their vitality. It is not necessary to assume the presence of something toxic in the oat kernel to account for the injury which results from the presence of a high content of oats in a monotonous food mixture taken over a considerable period. Oats produce feces of a pasty character which makes their elimination difficult, and in all probability tend to debilitate the animal. . . .

"When the oat kernel is supplemented with casein, a suitable salt mixture, and butter fat, growth may proceed to the normal adult size at the normal rate in some animals, but in general growth is slower than the normal rate... The authors have been able to secure reproduction with these rations in but a single instance, and the young survided but one day."

Further investigations on this subject are in progress.

The influence of temperatures above freezing on the changes in chemical composition, bacterial content, and histological structure of the flesh of the common fowl, M[ARY] E. PENNINGTON, J. S. HEPBUEN, E. Q. St. JOHN, and E. WITMER (Jour. Biol. Chem., 29 (1917), No. 2, pp. XXXI, XXXII).—The animal heat was removed from freshly killed chickens by storage at about 0° C. for 24 hours. Some of the birds were then analyzed as "freshly killed chickens." One lot was stored at the average temperature of 23.9° C. for a period of four days at the maximum; another in a household refrigerator at a temperature of 7.2 to 12.8° C. for a period of seven days at the maximum; and a third lot at a temperature of 0° C. for a period of three weeks at the maximum. Analyses of birds from each of these lots showed that while the total nitrogen content of the muscle remained unchanged the partition of the nitrogen underwent changes in all three cases.

"At all three temperatures of holding the amino acid and basic nitrogen increased at the expense of the protein nitrogen, usually in a progressive manner. The most striking change in the fat constants was an increase in the acid value, which became progressively greater as the period of holding lengthened. Both the formation of amino acid and basic nitrogen and the increase in the acid value of the fat occurred most rapidly at the temperature of the room, least rapidly at that of the chill room. . . . The bacteria, which grow under aerobic conditions, increased in both the muscles and the skin at all three temperatures of holding. The increase was enormous in the chickens kept in the room and was less marked, though distinct, in those kept in the refrigerator and in the chill room. The increase usually became greater as the period of holding lengthened."

Changes were also noted in the histological structure of the animals in all cases, these changes depending both on the temperature and the time of holding.

"The changes which occurred during holding in the chill room for three weeks were about equal to those occurring during holding in the house refrigerator for five to seven days. The changes which took place during holding in the house refrigerator for five days were less than those taking place during holding in the room for two days."

The influence of temperatures below freezing on the changes in chemical composition, bacterial content, and histological structure of the flesh of the common fowl, M[ARY] E. PENNINGTON, J. S. HEPBUEN, E. Q. ST. JOHN, and E. WITMER (Jour. Biol. Chem., 29 (1917), No. 2, pp. XXXIII, XXXIV).—This paper presents a brief report of chemical, bacteriological, and histological studies of chickens which, after having been frozen hard, were stored at temperatures varying from —9 to —13° C. for periods as long as two years.

Analyses and organoleptic tests showed that no loss of food value occurred while the chickens were in the freezer, and the birds were still wholesome and nutritious, the only appreciable changes being a loss in flavor after holding for a priod longer than nine months. The muscular tissue showed a progressive loss of water while the chickens were held in the freezer. The total nitrogen of the muscle remained unchanged, but changes occurred in the partition of the nitrogen which indicated the occurrence of a slow but distinct proteolysis. The hydrolysis of the fat and the digestion of the protein occurred much less rapidly than in the case of birds held at temperatures above freezing. These chemical changes were believed to be due to an enzymatic rather than to a bacteriologic cause. Certain characteristic changes took place in the histological structure of the cells of the muscle, nerves, and blood vessels.

"The changes here recorded were most marked after the normal commercial period of freezer storage had been exceeded. . . . The changes in chemical

composition during holding in the freezer for one year were about equal to the changes which occurred during holding in the chill room for three weeks."

A study of food fishes. The complete analysis of 20 common food fishes, with especial reference to a seasonal variation in composition, E. D. Clark and L. H. Almy (Jour. Biol. Chem., 29 (1917), No. 2, p. XXII).—In general, little variation was found in the amount of nitrogenous and ash constituents. The amount of fat varied considerably and depended upon the season, age of the fish, and relation to the time of spawning and feeding. With migratory fish, such as shad, bluefish, weakfish, and mackerel, the fat content varied from less than 0.5 to over 16 per cent, while typical bottom fish, like cod, haddock, and flounders, had a minimum amount of fat which varied but slightly as compared with the surface and migratory species.

The grayfish.—Try it (U. S. Dept. Com., Bur. Fisheries Econ. Circ. 22 (1916), pp. 8, fig. 1).—This circular describes the grayfish (commonly known as dogfish) and discusses its food value.

Grayfish is said to have been eaten for some time on the shores of the Mediterranean and in northern Europe, and the Bureau of Fisheries recommends that it be used for food purposes in this country. It is said to be excellent when eaten fresh, canned, salted and dried, or smoked. The circular contains a number of recipes for its preparation.

Tenth annual report of the chemical department of the [Indiana State] Laboratory of Hygiene, H. E. Barnard (Ind. Bd. Health, Ann. Rpt. Chem. Div. Lab. Hyg., 10 (1915), pp. 85).—The work of the laboratory during the year ended September 30, 1915, is reviewed. This included analyses of 652 samples of different foods, of which 481 were found to conform to existing standards of composition and labeling. The work also included the examination of 246 samples of drugs and patent medicines and the sanitary inspection of a large number of food esfablishments, including canneries.

Annual report of the food and drug commissioner, F. H. FRICKE (Ann. Rpt. Food and Drug Comr., Missouri, 1916, pp. 45, pls. 5).—This report covers the work of the food and drug department for the year ended December 31, 1916. This included the examination of a large number of samples of miscellaneous food products, the inspection of miscellaneous food establishments, etc.

[Food and drug inspection in North Dakota], E. F. Ladd and Alma K. Johnson (North Dakota Sta. Spec. Bul., 4 (1917), No. 11, pp. 259-330, figs. 3).— This bulletin contains a report on The Composition of Canned Corn, by R. E. Remington, including a large number of analyses; the results of the examination of 35 samples of tincture of iodin, by Matty Jongeward; and the results of the sanitary inspection of a large number of groceries, restaurants, hotels, slaughterhouses, etc.

California pure foods and drugs acts, food sanitation act, cold storage act ([Sacramento], Cal.: State, 1916, pp. 160).—The texts are given of the acts as amended to 1915, with rules and regulations for their enforcement, standards of purity, etc.

The dairy and food laws of the State of Michigan (Lansing, Mich.: State, 1915, pp. 201).—This is a compilation of the texts of the laws and digests of court decisions relating thereto.

Manual for army bakers, 1916 (War Dept. [U. S.], Doc. 563 (1917), pp. 123, pl. 1, figs. 20).—This book contains information regarding the nature, care, and storage of different food materials, recipes for the preparation of bread, and general information regarding post and field bakeries and baking equipment.

Economical dishes for wartime, FLORENCE A. GEORGE (Birmingham [England]: Cornish Brothers, Ltd., 1916, pp. 48).—A compilation of recipes.

The rural school luncheon (Regina, Canada: Govt., 1916, pp. 40, pl. 1, Ags. 9).—This pamphlet, which was issued by the Department of Education, Saskatchewan, as Household Science Circular No. 1, contains information regarding the equipment and supplies to be furnished by the school board and the duties of the teacher and the mothers, and gives recipes and directions for the preparation of the luncheon.

Studies in carbohydrate metabolism, XIV-XX, Louise McDanell and F. P. Underhill (Jour. Biol. Chem., 29 (1917), No. 2, pp. 227-232; 233-243; 245-250; 251-254, ftg. 1; 255-263; 265-272, ftg. 1; 273-280).—Seven articles are here presented.

XIV. The influence of alkali administration upon blood sugar content in relation to the acid-base-producing properties of the diet.—The data here reported indicate that the injection of sodium carbonate is as ineffective in altering the blood sugar content of normal laboratory animals (rabbits) when maintained either upon acid-forming or base-forming diets as is the case with animals receiving a mixed diet.

XV. The influence of acid-forming and base-forming dicts upon blood sugar content.—Experiments with normal laboratory animals (rabbits) showed that the blood sugar content was not changed by variations in the acid-base content of the diet which were sufficient to cause a marked change in the hydrogen ion concentration of the urine.

XVI. The relation of epinephrine glycosuria to dosage and to the character of the diet.—The following conclusions are drawn in part from the data reported:

With a sufficient quantity of food, laboratory animals (rabbits) maintained upon a mixed diet excreted larger amounts of sugar after epinephrine administration than when maintained upon either an acid-producing diet or one yielding a basic ash. During a base-forming diet a somewhat larger output of sugar occurs after injection of epinephrine than is the case under similar conditions with an acid-producing diet. It is possible that there is a greater glycogen storage upon a base-producing diet than upon a diet yielding acid ash.

XVII. Further experiments upon the influence of the intravenous injection of sodium carbonate upon epinephrine hyperglycemia and glycosuria.

XVIII. The relation of diet to the glycogen content of the liver.—Studies of the influence of the diet upon the glycogen content of the liver were carried out with normal laboratory animals (rabbits).

It was found that a base-forming diet is somewhat more efficient in the formation of glycogen than an acid-producing diet. These results are in agreement with those of other investigators, who have found that an excess of alkali contributes to the accumulation of glycogen. However, it was also demonstrated that a large storage of glycogen may take place upon an acid-forming diet when sufficient food is ingested.

XIX. The influence of the intravenous injection of sodium carbonate upon the hyperglycemia and glycosuria following the subcutaneous administration of glucose.

XX. New experiments upon the mechanism of salt glycosuria.

A chemical study of prolonged inanition, R. E. Swain (Jour. Biol. Chem., 29 (1917), No. 2, p. XXXV).—This is a brief report of observations on a 30-year-old man, who subjected himself to a starvation period of 60 days.

Preliminary observations on the regulation of the calcium excretion in the dog, M. H. Givens (Jour. Biol. Chem., 29 (1917), No. 2, p. XXIV).—In a laboratory animal (dog) maintained in nitrogenous equilibrium for 60 days, negative calcium balance was brought about by a diet of meat, lard, and cracker meal. The substitution for cracker meal, on the basis of nitrogen and calorie equivalent, of dried skim milk and sucrose resulted in an approach toward a

calcium balance. No effect was produced on the calcium output by the addition of sodium bicarbonate to either of these diets. The addition of hydrochloric acid to the meat-cracker diet produced a prompt increase in the excretion of calcium by way of the kidneys, and the addition of the acid to the dried-skimmilk diet produced an increased urinary excretion of calcium, though not at the expense of the fecal output.

The active constituent of the thyroid: Its isolation, chemical properties, and physiological action, E. C. Kendall (Jour. Biol. Chem., 29 (1917), No. 2, pp. XXIX, XXX).—The active constituent separates in microscopic needles. It may be precipitated as free base or in salt form. Its chemical properties depend upon the degree of purification and the presence of other substances, and its physiological activity depends upon the amount administered and the susceptibility of the individual.

The use of pancreatic vitamin in cases of malnutrition, W. H. Eddy (Jour. Biol. Chem., 29 (1917), No. 2, pp. XVI, XVII).—A report of a preliminary study which suggests the possibility of stimulating assimilation by the artificial feeding of pancreatic vitamins.

# ANIMAL PRODUCTION.

The associative digestibility of corn silage and cottonseed meal in steer rations, II, P. V. Ewing, C. A. Wells, and F. H. Smith (Georgia Sta. Bul. 125 (1917), pp. 149-164, fig. 1).—This is the second progress report of an investigation at the station on the associative action of feeds, or the influence of one ingredient of a ration on the digestibility of the nutrients of the other ingredient (E. S. R., 34, p. 169). The feeds used were silage made from corn from which the ears had been removed, and screened choice cottonseed meal. Of the six rations involved in the experiments two were silage alone, two silage and cottonseed meal, and two cottonseed meal alone. Only one of the two rations of cottonseed meal gave satisfactory digestive trials. High-grade two-year-old Shopthorn steers were used.

In the digestive trials, which lasted ten days each, the feces composite only were collected. An improved form of feces duct, which is described, was used. The feces sample was divided into three fractional parts by a method which is described, one fraction being assumed to represent the corn silage residue. Data are tabulated showing the feed schedule, analyses of feeds used, a general summary of the digestion trials, analyses of the different fractional parts of the feces, the utilization of the nutrients consumed, and gains and losses in digestibility due to food combination.

In general, it was found that with the feeds used there were no appreciable differences in the digestibilities of the nitrogen and fats as a result of the combination of the two feeds. When silage and cottonseed meal were fed together in the proportion of 3.4:1, the digestibility of the total dry matter was 4.62 per cent below the theoretical standard; and when these feeds were combined in the proportion of 7.7:1 the digestibility of the total dry matter exceeded the theoretical standard by 1.1 per cent. There was an appreciable gain in digestibility of the ash and nitrogen-free extract in both rations in which the feeds were combined, but an appreciable loss in the digestibility of crude fiber. In attempting to ascertain the cause of these gains and losses of digestibility by an examination of the fractions of the feees, it was concluded that a steer macerates his food approximately four times as well when fed silage alone as when fed silage and cottonseed meal in the proportion of 3.4:1, and twice as well when fed silage alone as when fed silage alone as when fed the mixture in the proportion of 7.7:1. The digestibility of the dry matter and crude fiber of silage seemed

to be proportionate to the extent or completeness of maceration or physical disintegration. The feeding of silage and cottonseed meal in combination apparently increased the digestibility of total ash in the cottonseed meal.

It is stated that "heavy cottonseed meal feeding tends to lower the nutritive value of the silage fed along with it and the most economically used rations are those containing a maximum amount of silage with a minimum amount of cottonseed meal. The nutrients of cottonseed meal and silage are not digested in the same proportions when fed alone and in combinations."

Animal husbandry experiments (Iowa Sta. Rpt. 1916, pp. 25, 26).—In fattening experiments with 2-year-old steers, rations of silage with about one-fourth to one-half of a full ration of corn returned from \$2 to \$6 more profit per head than when the steers were hand-fed or self-fed. The results of four years' cooperative beef cattle experiments in Monona County indicate that baby beef can be profitably raised and fed out on the average Iowa farm under present conditions.

The results of an experiment in which a Shorthorn bull and Galloway cows were originally crossed and their offspring intercrossed indicate that "the white color of the Shorthorn type is due to the lack of a factor E for extension, which is present in colored cattle. The extension factor operates on both black and red pigment. There is another type of white in cattle which does not involve the loss of the extension factor. The previously assumed allelomorphic nature of red and black, and also of horned and polled, is demonstrated. In regard to its bearing on farm practice, the experiment shows that breeders of polled cattle may introduce superior horned animals into their breeding herds without danger of seriously losing ground."

[Animal husbandry studies], E. J. Iddings and C. W. Hickman (Idaho Sta. Bul. 92 (1916), pp. 4-7).—Continuing the work in sheep breeding and management (E. S. R., 34, p. 767), information was obtained on the yield and composition of milk of the different breeds in the test. The following table gives a summary of these data together with five years' weights of fleece and three years' birth weights of lambs, lambing percentages, and average daily gains of lambs to three months of age.

Results of tests in sheep breeding and manage	agement.
-----------------------------------------------	----------

Breed.	Weight of fleece.	Burth weight of lambs.	Lambing percentage.	Daily gain per lamb.	Daily milk yield per ewe.	Milk fat.	Total milk solids.
Rambouillet Hampshire Shropshire Southdown Cotswold	Pounds. 14.1 7.8 11.2 7.3 15.1	Pounds. 8.3 9.4 8.2 7.1 7.0	147 173 154 116 142	Pounds. 0.45 .61 .49 .39 .45	Pounds. 2.32 2.38 1.65 1.22 2.46	Per cent. 8.82 6.64 9.02 8.60 8.62	Per cent. 14. 66 11. 98 14. 86 14. 61 14. 98

No adequate explanation has thus far been found for differences noted in the growth of lambs.

Silage from peas and oats and from wheat and vetch was used with satisfactory results in maintaining beef cattle during the winter. It was found that silage from either of these mixtures readily replaced corn silage for milk production.

The results of hogging off 3.88 acres of Canada field peas are summarized in the following table:

Results in tests of hogging off field peas.

Lot.	Area in acres.	Number	Average initial weight per head.	Days on test.	Averag	Net profit per acre.	
		of pigs.			Per head daily.	Per acre.	(Pork 8 cents per pound.)
1 2	0.82 .84 .70 1.52	14 26 16 18	Pounds. 88.6 81.7 125.0 160.0	28 21 21 35	Pounds. 1.16 1.45 1.32 1.09	Pounds. 553 940 631 450	\$44. 24 54. 44 50. 48 36. 00

The pigs in lot 2 were fed, in addition to the peas, rolled barley at the rate of 2 lbs. per 100 lbs. of live weight, or a total of 1,162 lbs. This barley was charged at the rate of \$30 per ton. The plat on which lot 4 grazed was sown with a mixture of 80 lbs. of field peas and 20 lbs. of wheat per acre.

In tests of nitrogenous supplements for barley for pigs during the winter of 1915-16, chopped alfalfa showed a relatively high feeding value. Tankage produced relatively cheap and the largest gains.

Lamb and sheep feeding experiments, E. J. Iddings (Idaho Sta. Bul. 89 (1916), pp. 3-14, figs. 3).—In continuation of work already noted (E. S. R., 29, p. 870), results are reported of feeding experiments completed in 1914 with 511 lambs and 223 ewes and wethers at Caldwell, and 27 lambs at Moscow.

At Caldwell the tests were conducted in open lots, the pens being so arranged as to permit little exercise. The lambs were divided into three lots of approximately 170 each and fed for 109 days. The lambs in lot 1 received alfalfa hay ad libitum and a grain mixture of corn and barley (1:3). They were started on 1 lb. of grain per head daily, which was increased to 1.5 lbs. These lambs made an average daily gain of 0.28 lb. per head at a feed cost of 6.14 cts. per pound of gain, and returned a profit, after deducting all expenses, of 59 cts. per head. The lambs in lot 2 were fed alfalfa hay alone for the first month of the test and then were given a grain mixture which averaged 60 per cent of barley, 33 per cent of corn, and 7 per cent of oats. They made an average daily gain of 0.24 lb. per head at a feed cost of 5.85 cts. per pound of gain and a net profit of 70 cts. per head. The lambs in lot 3 were fed alfalfa hay and grain throughout the test. For the first 25 days the grain consisted of barley and oats (3:1), and thereafter of barley alone. The lambs in this lot gained an average of 0.28 lb. per head daily at a feed cost of 5.58 cts. per pound of gain and a net profit of 77 cts. per lamb.

The ewes and wethers were fed for 128 days a ration of cut mixed grain hay and whole alfalfa hay. After about two months they were also fed a grain ration of oats, which was changed after a few days to a mixture of ground barley, ground wheat, and ground corn (1:1:1). They made an average daily gain of 0.14 lb. per head at a feed cost of 8.62 cts. per pound of gain and a net profit of 8 cts. per head. In these experiments the following values per ton for hay were realized after deducting all expenses: For lambs, lot 1 \$10.53, lot 2 \$12.42, and lot 3 \$12.47, and for ewes and wethers \$6.40. The prices charged for feeds were alfalfa hay \$5 and cut hay \$6 per ton; barley and oats \$1 per hundredweight, with 10 cts. for grinding; corn \$1.40 per hundredweight, with 10 cts. for cracking; and ground wheat \$1.20 per hundredweight.

In the Moscow experiment 27 farm grown lambs, averaging about 101 lbs. each, were fed for 55 days under shelter. The nine lambs in lot 1 were fed mixed hay and a mixture of barley and field peas (3:1). They made an average daily gain of 0.281 lb. per head, at a feed cost of 9.07 cts. per pound

of gain. The nine lambs in lot 2 were fed mixed hay and a mixture of barley and bran (3:1). They made an average daily gain of 0.274 lb. per head, at a feed cost of 8.5 cts, per pound of gain. The nine lambs in lot 3 were fed mixed hay and a mixture of barley and linseed cake (3:1). They gained an average of 0.318 lb. per head daily at a feed cost of 8.71 cts, per pound of gain. All the lambs received alfalfa hay during the last eight days of the test. The grain mixtures were fed either ground or rolled. The lambs were bought at 5 cts, per pound and sold for 6 cts. Each lot returned a profit, the average for the three lots being 41 cts, per head. The charges per ton for feeds in this experiment were hay \$8, barley \$24, bran \$20, linseed cake \$42, and field peas \$30.

Suggestions are given for feeding range lambs.

[Live-stock experiments] (New Mexico Sta. Rpt. 1916), pp. 51-55).—In an experiment with four lots of seven pigs each in which lot 1 was fed all the concentrates the pigs would eat within a reasonable time, lots 2 and 4 a concentrate ration at the rate of 2 lbs. per 100 lbs. live weight, and lot 3 1 lb. of a concentrate and 8 lbs. of skim milk per 100 lbs., all of the lots having access to good alfalfa pasture, the results were favorable to lots 2 and 4. However, these pigs required an additional feeding period on a full ration to fit them for market.

In a test with two lots of 16 pigs each on alfalfa hay, one lot fed a full ration of ground milo maize and a small quantity of skim milk was ready for market 30 days earlier than the other lot which received a limited amount of these supplements. In another test with pigs on alfalfa hay, one lot was fed a mixture of milo maize and mesquite beans (2:1), and the other lot had a full ration of ground milo maize. The results indicate that with pork at 10 cts. per pound, milo maize \$1.50 per 100 lbs., and alfalfa hay 50 cts. per 100 lbs., mesquite beans are worth \$1.30 per 100 lbs. Some difficulty was experienced in getting the beans properly ground for the pigs. This was best accomplished by grinding the beans and the grain together in the proportions wanted.

Data from feeding experiments at the Tucumcari dry-land substation indicate that good results may be obtained in feeding range steers wholly on dry-land crops.

[Grazing experiments with pigs] (Idaho Sta. Bul. 92 (1916), pp. 46, 47, 53, 54, fig. 1).—In tests at the Caldwell substation, reported by O. D. Center and C. B. Hampson, three sows and 19 pigs were placed on 1 acre of alfalfa pasture on May 18, 1915. On June 5 three sows and 14 pigs were added to the lot. This drove was insufficient to keep the alfalfa pasture closely grazed, and on June 27 588 lbs. of cured alfalfa hay was harvested from the acre. The animals were fed 25 lbs. of barley and 140 lbs. of skim milk daily. By August 11 these sows and pigs had gained 1,211 lbs. The pigs were then grazed on 1 acre of peas for 19 days, receiving in addition 11 lbs. of soaked barley and 20 lbs. of skim milk daily, and gained 155 lbs. on this acre. On August 30 they were turned on a second acre of peas and grazed for 13 days, and on September 11 on an acre of peas and wheat in combination for 17 days. The barley and skim milk were continued in the same quantity. The pigs gained 429 and 447 lbs. on these acres, respectively.

At the Gooding substation, in work reported by J. S. Welch, 21 young pigs on one-half acre of alfalfa, supplemented by 3.284 lbs. of grain and 1,878 lbs. of skim milk, made a gain of 1,362 lbs. in 131 days. In hogging off experiments, five pigs grazed on 0.238 acre of peas for 27 days and produced gains at the rate of 496 lbs. per acre. On a plat of 0.23 acre of peas and wheat five pigs grazed for 39 days, making gains at the rate of 565 lbs. per acre. On 0.216

acre of horse beans planted too late for high yields, five pigs grazed for 20 days and gained at the rate of 394 lbs. per acre.

[Feeding experiments with pigs] (Washington Sta. Bul. 136 (1917), pp. 8, 9).—In an experiment with newly weaned pigs, 73 head were divided into three lots and placed in a dry lot, pea and oat pasture, and alfalfa pasture, respectively. In addition each group received a ration of 95 per cent of rolled barley and 5 per cent of commercial pig meal for 24 days, and thereafter a ration of 92 per cent of rolled barley and 8 per cent of tankage. On changing the dry lot to tankage the gains were practically doubled and the amount of concentrates required per pound of gain reduced from 5.5 to 3.93 lbs. The change to tankage increased the gains of the pea and oat pasture group from 0.35 to 0.69 lb. per head daily, and decreased the concentrates from 4.09 to 3.26 lbs. per pound of gain. The alfalfa pasture group gained 0.31 lb. per head daily on the pig meal and 0.836 lb. on tankage. The amount of concentrates required per pound of gain by this lot was 5.24 lbs. on the pig meal and 3.73 lbs. on tankage.

A group of pigs that had been wintered around straw stacks and in stubble fields with no grain and a group that had been fed a growing ration through the winter were subsequently finished on rolled barley and shorts (3:1). The poor wintering had not destroyed the ability of the pigs to grow and fatten, but had limited their capacity for food consumption and delayed their finishing.

In a comparison of wheat v, barley, for fattening barrows, it required 4.47 lbs. of wheat, or 5.52 lbs. of barley, to produce a pound of gain.

Twelve pigs on alfalfa pasture with a supplemental ration of 90 per cent of rolled barley and 10 per cent of tankage in a self-feeder, and 100 lbs. of skim milk daily for 74 days, produced gains at 5.5 cts. per pound, not considering the value of the pasture.

Self-feeders for fattening swine, L. A. Weaver (Missouri Sta. Bul. 144 (1917), pp. 3-17, figs. 2).—Some of the results of experiments at the station on the value and limitations of self-feeders for swine are given in the following table:

Self-feeding v. hand-feeding of pigs.

Lot No.	Ration,	Number	A verage initial	Duration of test.	Average daily gain	Feed per pound of gain.		
ATU,		of pigs.	weight.	Ot test.	per head.	Amount.	Cost.	
			Lhs.	Days.	Lbs.	Lbs.	Cents.	
1	Corn and tankage (12:1)—(self-fed).	7	112.0	56	1. 97	4.00	6, 40	
2	Corn and tankage (12:1)—(hand-	7	110 0	-0		4.40		
3	fed) Corn, shorts, and tankage (self-fed).	10	112. 0 77. 4	56 60	1. 98 1. 69	4. 18 4. 19	6. 68 5. 75	
4	Corn, shorts, and tankage (8:2:1)-				1.00	44.10	0.10	
5	(hand-fed) Corn, shorts, and tankage (self-fed).	10	77. 4	60	1. 51	4. 04	5. 66	
6	Corn and tankage (self-fed)	10 10	137. 7 136. 4	42 42	2. 00 1. 77	3. 63 3. 50	5. 07 5. 05	
7	Corn and tankage(12:1)—(hand-fed)	12	150. 2	42	1. 76	4. 07	5. 78	
8	Corn and tankage (self-fed)	10	122. 2	60	1.62	4. 61	6. 43	
a	Corn and tankage (12:1)—(hand- fed).	10	119. 8	60	1.54	4. 62	6, 56	
10	Corn, shorts, and tankage (self-fed).	10	121. 0	60	1. 80	4. 55	6.31	
11	Corn, shorts, and tankage (8:2:1)-							
12	(hand-fed)	10	122. 7	60	1.68	4.38	6.35	
13	Corn, shorts, and tankage (9:3:1)—	8	39. 98	112	1.05	3. 84		
	(hand-fed)	8	39. 91	112	. 95	S. 65		

In addition to the above rations the animals had access to a mixture of copperas, Glaubers salts, common salt, sal soda, and sulphur. The pigs of lots 12 and 13 were grazed on rape pasture, which furnished abundant forage through-

out the test. In the other experiments the pigs were fed on dry lots. In all the tests, except with lots 1 and 2, the feeds in the self-feeders were unmixed. The proportions in which the unmixed feeds were consumed from self-feeders were as follows:

Lot 3, corn, shorts, and tankage (17.5:5.6:1); lot 5, corn, shorts, and tankage (18.5:8.1:1); lot 6, corn and tankage (8.9:1); lot 8, corn and tankage (17.1:1); lot 10, corn, shorts, and tankage (20.66:3.93:1); and lot 12, corn, shorts, and tankage (11.6:0.23:1).

The cost of gains in these experiments was figured on the basis of 75 cts. per bushel for corn, \$1.40 per 100 lbs. for shorts, and \$2.50 per 100 lbs. for tankage.

The author states that while these results do not warrant definite conclusions they indicate that "fattening hogs fed with a self-feeder gain more rapidly than when hand-fed in the usual manner. There is no difference in the economy of gain which can be accredited to the method of feeding. . . . When each feed is placed in a separate feeder the hogs will choose the different feeds, so that the gain will be both rapid and relatively economical. This will perhaps be true only when each feed is supplied in abundance. . . .

"It is apparent that the advantage which the self-feeder method will have in any specific instance over hand-feeding, in regard to rate of gain, will depend to a large degree upon the ability of the person doing the hand-feeding to feed so that the hogs will consume a maximum amount of feed. In practically all cases, when the self-fed hogs gained more rapidly than those which were hand-fed, they also consumed more feed. In a similar manner the relative efficiency of the self-fed ration, and the same feeds hand-fed, will depend upon the ability of the feeder to combine properly the feeds used."

[Poultry husbandry studies], P. Moore (Idaho Sta. Bul. 92 (1916), pp. 28-30).—Four pens of 25 White Leghorn pullets each received the following rations for one year: Pen IV a grain ration of peas, wheat, and corn (10:14:6), and a mash of bran, shorts, corn meal, wheat meal, pea meal, linseed meal, and charcoal (3:3:1:1:1:6:1), the nutritive ratio being 1:4.2; pen V a grain ration of corn and wheat (6:10), and a mash of bran, shorts, corn meal, wheat meal, beef scrap, and charcoal (2:1:1:1:3:1), with a nutritive ratio of 1:42; pen VI the same as pen IV, except that the grain ration was in the ratio of 1:10:5, and the mash three parts of linseed meal to one part each of the other ingredients, the nutritive ratio being 1:5.5; and pen VII the same as pen V, except that the mash ingredients were in the ratio of 2:2.5:1:1:1.5:1, and the nutritive ratio 1:5.5. During the year pen V produced 55.8 per cent more eggs than pen IV, 51.1 per cent more eggs than pen VI, and 35.2 per cent more eggs than pen VII. The percentage of eggs under 2 oz. in pen IV was 46.5, in pen V 15.2, in pen VI 41.9, and in pen VII 17.5.

[Poultry experiments] (Iowa Sta. Rpt. 1916, pp. 27, 28).—Feeding experiments carried on at the station indicate that corn is equal, pound for pound, if not superior, to wheat as the basis of a ration for feeding both growing and laying stock. Corn gave results superior to wheat as a food for laying stock during warm weather. To obtain satisfactory results in feeding both wheat and corn, it was found necessary to use some animal food, such as high-grade tankage, meat meal, or skim milk, and also to supplement the grain with mineral food rich in lime and phosphate, such as bone meal.

Experiments indicate that capon production is profitable with the larger breeds of general purpose fowls. Capons produced a net profit of from 25 to 40 per cent more than cockerels.

In experiments with nest eggs of various kinds, it was found that hens prefer to lay in nests provided with the natural egg.

Mating and early hatching, V. G. Aubry (New Jersey Stas. Hints to Poultrymen, 5 (1917), No. 4, pp. 4).—Brief directions are given for selecting and mating fowls for increased egg production, together with an outline of the advantages of early hatching.

Colony brooding, V. G. Aubry (New Jersey Stas. Hints to Poultrymen, 5 (1917), No. 6, pp. 4).—Brief directions are given for the artificial brooding of chicks by the colony plan.

Preparing birds for exhibition, R. F. IBVIN (New Jersey Stas. Hints to Poultrymen, 5 (1916), No. 1, pp. 4).—Brief directions are given for selecting, conditioning, training, washing and cleaning, and shipping poultry for exhibition.

The Vineland international egg laying and breeding contest, H. R. Lewis (New Jersey Stas. Hints to Poultrymen, 5 (1916), No. 2, pp. 4).—This circular briefly describes the three-year international egg laying and breeding contest being conducted at Vineland, N. J., and points out ways by which the poultrymen of the State may follow the results of the contest.

Our state department of poultry husbandry, its organization and activities, H. R. Lewis (New Jersey Stas. Hints to Poultrymen, 5 (1917), No. 5, pp. 4).—A brief outline is given.

# DAIRY FARMING—DAIRYING.

The nutrients required to develop the bovine fetus, C. H. Eckles (Missouri Sta. Research Bul. 26 (1916), pp. 3-36, figs. 4).—The author reviews investigations by others upon the utilization of food by mammals for the development of the fetus and reports experiments with cows from which it is concluded that a cow can produce a fetus on the same ration that will maintain her when dry and farrow, or that the amount of nutrients necessary to develop the bovine fetus is so small that it can not be measured by ordinary methods of experimentation.

Four cows were kept during the entire period of gestation on a ration found by six months' trial to be only sufficient to maintain them at uniform weight when not pregnant and not producing milk. These cows developed calves of normal size on this ration, and one cow weighed 48 lbs. more after the calf was dropped than when bred and the other weighed only 17 lbs. less. This result was confirmed by two additional cows, the feeding of which was regulated during gestation by that required to maintain a dry farrow cow at uniform weight. One of the Jersey cows developed a normal fetus while receiving less than a maintenance ration during the period of gestation.

The author states that these results may be due to one or more of three possible factors—(1) better use of feed during gestation, (2) decreased maintenance during pregnancy, and (3) small amount of dry matter in fetus. Conclusions with reference to these factors are summarized as follows:

"While the data taken are not very satisfactory, the indications are that the coefficient of digestibility is not changed by pregnancy. The data do not make it possible to conclude definitely that the maintenance of the animals is decreased by pregnancy, but it is thought this is probable and could be accounted for by the animal being quieter when in this condition. The data show that the amount of dry matter contained in the fetus and its accompanying fluid and membranes is very small. The small feed requirement necessary to supply the dry matter of the fetus, together with the amniotic fluid and placenta, is either too small to be measured on account of the length of time represented or it is offset by the saving due to decreased maintenance.

"Four Jersey calves analyzed at birth contained an average of 73.09 per cent of water. Data available indicate that breed is not a factor influencing the composition of the new-born calves. The amniotic fluid weighs about 30 dbs. and contains approximately 95 per cent water. The placenta weighs about 18 lbs., of which approximately 85 per cent is water. A Jersey cow produces a total of only 15 or 20 lbs. and a Holstein 20 or 25 lbs. of dry matter in the fetus and its accompanying fluid and membrances. On the dry-matter basis a Jersey calf at birth is equivalent to from 110 to 170 lbs. of Jersey milk. In the Holstein breed the calf at birth will contain as much dry matter as from 200 to 275 lbs. of Holstein milk.

"Using [one of the Jersey cows] as typical of all, it is shown that she produced during one year 1,263 lbs. of dry matter in her milk. During this time 2,828 therms of energy were available in her ration for this milk production in excess of maintenance. Her calf with placenta and amniotic fluid contained approximately 24 lbs. of dry matter, or 1.9 per cent as much dry matter as in her milk for one year. If the calorific value of the solids in the fetus are considered equivalent pound for pound to that of the solids in the milk it would appear by calculation that this cow would require 1.9 per cent as much energy as was used for her milk production, or 47.7 therms. The actual energy in the fetus and its accompanying fluid and membrances calculated from the weights and composition was 56.4 therms, a figure surprisingly close to the calculated requirement of 47.7 therms.

"All the data available indicate that the weight of a calf at birth is not ordinarily influenced by the ration received by the mother during gestation. This is especially true with reference to the energy value of the ration, but may not hold good when the ration has been decidedly deficient in some constituent for a long period."

The data are tabulated and discussed in detail, and feed and weight records during pregnancy for each animal are shown by graphs.

Effects of feeding cottonseed products on the composition and properties of butter, C. H. Eckles and L. S. Palmer (Missouri Sta. Lescarch Bul. 27 (1916), pp. 3-44, figs. 3).—The investigations reported in this bulletin were confined chiefly to a study of the effects that the feeding of cottonseed products exerts on the physical and chemical constants of milk fat and on the standing-up quality of butter and its keeping and market qualities. Studies were also made on the cause of the effects, as well as several minor studies, such as the persistence of the effects and the typical characteristics of butter produced where cottonseed products are fed according to the ordinary practice in the South. The investigations of other workers in this field are reviewed, and results secured by them are tabulated with respect to the effect of the character of the roughage and the amount of cottonseed products fed upon the milk fat and butter.

In studying different phases of this subject at the station, 23 experiments were conducted in which 43 pure-bred animals of the university herd were used. There were 177 periods usually lasting about two weeks, in which samples were taken, and 2,033 chemical determinations and experimental observations were made, each in duplicate and frequently in triplicate. Of the great amount of data collected only those are reported which have a bearing upon the influence of feeding cottonseed products on the composition and properties of butter.

To test the effect of the oil in cottonseed products fed, eight cows were divided into four lots of two each and fed a basal ration of timothy hay and corn stover and a grain mixture of corn, bran, and linseed meal (4:2:1) in sufficient quantity to meet the demands of the Armsby standard. In addition,

lot 1 was fed enough cottonseed meal to furnish 0.4, 0.6, and 0.8 lb. of oil per head daily during different periods of the experiment, lot 2 enough cottonseed meats, i. e., the kernel of the seed from which the oil had not been pressed, to furnish the same amounts of oil as were fed lot 1 during the corresponding periods, and lot 3 was fed 0.4, 0.6, and 0.8 lb. of unrefined cottonseed oil per head daily in the respective periods. Lot 4 was later carried through an experiment identical with the cottonseed meal lot. An examination of the effects of these rations on the physical and chemical constants of the milk fat showed that the character of the effects was similar for each lot of cows. This was manifested by a marked drop in the saponification value and the Reichert-Meissl number and a marked increase in the iodin value and melting point. The data secured indicate that the effects on the constitution of milk fat which accompany the feeding of cottonseed meal are due to the oil in the meal, There was, however, some evidence that less pronounced effects were secured when the oil was fed in the cottonseed meal than when it was added directly to a ration containing no cottonseed meal, especially when not more than 4 lbs. of cottonseed meal was fed daily. In studying the standing-up quality of the butter small cakes of butter 3 cm. square and 1 cm. thick were placed in a water-jacketed oven and the temperature gradually raised a degree or two at a time until the cake of butter lost its shape. Temperatures were maintained at each point for one-half to three-quarters of an hour. In general the basal ration samples lost their shape at from 32 to 35° C., while all the samples during the feeding of meal, meats, and oil withstood a temperature of from 40 to 43°. The maximum effects in almost every case were secured when 6 lbs. of meal, or its equivalent of oil, was fed.

In a study made of the influence of the character of roughage on the effect of cottonseed feeding, two experiments were conducted in which timothy hay was the sole roughage, three cows being used in the first experiment and two in the second. Each animal consumed from 12 to 15 lbs, of hay daily in addition to the above grain mixture. In each experiment a basal period of from two to three weeks was followed by a period of three weeks in which 4 lbs, of the grain mixture of each animal was replaced by 4 lbs, of cottonseed meal. Averaging the results of the two experiments, it was found that there was a drop in the saponification value and Reichert-Meissl number and an increase in the iodin value and melting point of the milk fat during the cottonseed meal periods. With regard to the standing-up quality of the butter, it was found that the basal ration butter lost its shape at about 34°, and the cottonseed meal ration butter at from 40 to 41°. The butter made during the feeding of cottonseed meal was inferior in market quality and superior in keeping quality to that made during the basal period.

In three experiments with individual cows, alfalfa hay was fed with the above grain mixture. In certain periods of these experiments different amounts of cottonseed meal replaced equal quantities by weight of the grain mixture. It was found that the fat constants were very similar with like amounts of meal and that they were very similar to those obtained when the same amount of meal was fed with timothy hay or timothy hay and corn stover.

Cottonseed meal was fed with alfalfa hay and corn silage to two lots of seven and eight cows each. One lot was fed for 62 days a daily basal ration of from 30 to 45 lbs. of silage, from 7 to 11 lbs. of alfalfa hay, and from 6 to 11 lbs. of the usual grain mixture. The other lot was fed the same ration in a first and fifth period. During the three intervening periods the grain mixture was replaced pound for pound with 2, 4, and 6 lbs. of cottonseed meal, respectively. It was found that there was a striking lack of effect on the physical and chemical constants of the milk fat when cottonseed meal was fed with

[Vol. 37

these supplements. The only difference noted was an increase of 1.6° in melting point when the basal ration was changed to 6 lbs. of meal. Some effects on the butter due to the feeding of cottonseed meal were noted in this test, but these were not sufficient to detract from its market value. The basal ration butter lost its shape usually between 29 and 30°, while this was increased to 33° during the feeding of 4 lbs. of cottonseed meal and to 34.5° during the feeding of 6 lbs. of meal. Butter made during the feeding of cottonseed meal was decidedly superior in keeping quality as compared with the basal ration butter, and the larger the amount of cottonseed meal fed the better the keeping quality of the butter.

In order to investigate further the relation of roughage to the effects of cottonseed meal feeding, two lots of three cows each were fed for six consecutive periods, the first and sixth being basal periods and the others experimental. One lot received 0.6 lb. of crude cottonseed oil per cow in addition to the usual grain mixture in each of the experimental periods. The roughage was the same for each lot in the same period, but varied for the different periods. The results of this experiment confirmed those of the previous experiments, that silage feeding has a marked influence on the effects of adding cottonseed oil to the ration. It was also found that this influence was practically as great when from 20 to 25 lbs. of silage was fed as when from 30 to 40 lbs, was fed. Data from lot 2, which received no cottonseed oil, indicate that this result is due to the effect which silage itself exerts upon the milk fat constants. Moreover, the effect of sllage on the fat constants is in the opposite direction to that resulting from cottonseed meal or cottonseed oil feeding. From this the authors conclude that corn silage contains a specific substance which counteracts the effects of feeding cottonseed products. The nature of this counteracting material is being investigated. There was practically no difference in the composition of the milk fat due to the feeding of different dry feed rations in this experiment.

Several preliminary experiments were carried on in which cottonseed meal was fed with pasture, but omitted since the milk fat was clearly affected by underfeeding in the periods when no cottonseed meal was fed. In order to prevent underfeeding when animals were turned to pasture, an experiment was conducted with four lots of two cows each in which an ample grain ration supplemented mature pasture. Three of the lots received cottonseed products during their pasture period as a part of the grain mixture. The fourth lot received no cottonseed products. A fifth lot of two cows was fed 110 lbs. of green alfalfa per head daily during this experiment. The cottonseed products consisted of from 1 to 3 lbs. of cottonseed meal per head for the different lots plus an amount of crude cottonseed oil equal to the amount of oil in the cottonseed meal fed. The milk fat produced by the lot fed the usual grain mixture on blue grass pasture and by the lot fed green alfalfa was of similar composition. The principal change in the milk fat of these two lots due to the change from dry feed to pasture or green alfalfa was a decrease in the saponification value and melting point. The milk fat of the lots fed cottonseed products showed a marked decrease in the volatile fatty acids which resulted in a higher melting point. This was more or less proportional to the quantity of cottonseed products fed. With reference to the standing-up quality of the butter, it was found that when the cows were changed from the basal ration to pasture or green alfalfa there was a softening effect on the butter. However, when cottonseed products were fed on pasture there was a marked improvement in the standing-up quality of the butter as compared with butter from pasture rations containing no cottonseed products. When 0.6 lb. of cottonseed oil was fed the butter had a standing-up temperature of 38°. The

butter from the lots fed cottonseed products showed decidedly better keeping qualities than that from the other lots.

Two cows were placed upon the usual grain mixture, plus a little gluten meal for one cow, and timothy hay. After about a month 4 lbs. of cottonseed meal was substituted for 4 lbs. of the grain mixture for each cow and continued for 70 days. The meal was then increased to 5 lbs. for 30 days and to 6 lbs. for a final 30-day period. An examination of the physical and chemical constants of the milk fat of these cows throughout the test and of the keeping qualities and other characteristics of butter from these cows and from two herds of cows in Georgia, one of which had been fed cottonseed meal for six months and the other cottonseed for from four to six months, showed that the effects of feeding cottonseed products persist as long as such feeding is continued.

The results of the experiments are discussed and their practical application pointed out. It is stated that "the feeding of large quantities of cottonseed meal and whole cottonseed, as still practiced in many localities in the South, must be considerably modified if the butter industry of that part of the country is to attain its proper place in the butter industry of the nation. The use of the whole seed as a feed for dairy cattle is to be strongly discouraged on account of its excessive oil content." However, "the results indicate that 1 to 1.5 lbs. of whole seed, or 2 to 3 lbs. of cottonseed meal added to the ration of cows on fresh pasture will exert a decided improvement on the quality of the butter. Such a practice would also be of value in preventing the underfeeding which cows frequently suffer, often with serious results upon the milk flow, when first turned to pasture."

A list of the literature cited is included.

Silage feeding (Washington Sta. Bul. 136 (1917), p. 10).—In a progress report of experiments with four kinds of silage for dairy cows, it is stated that pea and oat silage compared favorably with corn silage, keeping in excellent condition and being relished and eaten as readily as corn by the cows. Wheat silage was slightly inferior to corn silage, both from the standpoint of milk production and the way the feed was relished by the cow. Clover silage fed in comparison with the other silage feeds showed little or no difference in its effect upon production. Cows failed to eat it quite so well at first, but upon becoming accustomed to it apparently ate it with as much relish as the corn silage.

[Feeding experiments with dairy cows] (New Mexico Sta. Rpt. 1916, p. 55).—A medium concentrate ration for dairy cows on average irrigated pasture did not prove profitable. The results of an experiment in the winter of 1915–16 favored the use of corn silage in a limited way to replace alfalfa hay for dairy cows.

[Machine milking versus hand milking], E. V. Ellington (Idaho Sta. Bul. 92 (1916), p. 17).—In tests of a mechanical milker with the university herd for eight months of one lactation period, it was found that with the same amount of labor necessary to milk the cows by hand they could be milked three times daily with the milking machine, with a resulting average increase in the milk flow of 22 per cent. One Holstein cow that was difficult to milk produced in eight months in 1916, with the mechanical milker, 11,795 lbs. of milk, containing 360 lbs. of fat. During similar periods on hand milking she gave, in 1915, 8,001.5 lbs. of milk, containing 274 lbs. of fat, and in 1914, 8,500 lbs. of milk, containing 336 lbs. of fat. It is stated that with hard-milking cows the milking machine apparently lengthens the lactation period.

Creamery records, O. W. HOLMES (*Idaho Sta. Bul. 90 (1916*), pp. 20).—This bulletin outlines and explains in detail the use of a proposed system of records for creameries. The forms illustrated and explained include a daily cream

receiving sheet, route or station report, patron's cream statement and check, sales slip, ledger sales sheet, cash record sheet for cashbook, daily sales record, daily make record, butter maker's report, monthly butter fat and overrun report, expense record, monthly inventory, check tag for cans and ice cream packers, and retail milk route report.

## VETERINARY MEDICINE.

Veterinary therapeutics, E. W. Hoare (Chicago: Alexander Eger, 1916, 3. ed., pp. XXIV+943).—The first of the three parts of this work (pp. 1-199) consists of a discussion of the diagnosis and general symptoms of disease; the care, management, and nursing of sick animals; the actions and uses of drugs; prescribing and administration of medicines; and veterinary pharmacy. The second part (pp. 200-556) is devoted to materia medica; and the third part (pp. 559-912) to special therapeutics. Numerous formulas are given in an appendix (pp. 864-906).

Biology, general and medical, J. McFarland (Philadelphia and London: W. B. Saunders Co., 1916, 3. ed., rev., pp. 457, pls. 3, figs. 151).—The third edition of the work previously noted (E. S. R., 24, p. 584). The subject matter has been corrected and some additions made to bring the material to date.

Microbiology, C. E. Marshall et al. (Philadelphia: P. Blakiston's Son & Co., 1917, 2. ed., rev. and enl., pp. XXIV+900, pl. 1, figs. 185).—This is the second edition of the work previously noted (E. S. R., 26, p. 372). The chapters originally by J. L. Todd have been revised by E. E. Tyzzer. A chapter on intestinal microbiology by W. J. MacNeal and one on microbial diseases of insects by Zae Northrup have been added.

Applied immunology, B. A. Thomas and R. H. Ivy (*Philadelphia and London: J. B. Lippincott Co., 1916, 2. ed., rev., pp. XVII+364, pls. 26. figs. 45*).— This is the second edition of the work previously noted (E. S. R., 34, p. 275). A number of additions and some new material have been incorporated.

The cause of anaphylaxis and the nature of the antibodies, J. Danysz (Compt. Rend. Acad. Sci. [Paris], 163 (1916), No. 26, pp. 985-989).—Experiments are reported which show that the antigens do not appear to be directly assimilable, but by their introduction produce substances which later transform them to assimilable products. This change consists of the formation of a precipitate which in nonfatal cases is again dissolved. It is indicated that the formation of the embolus in the blood vessel produces the symptoms of anaphylaxis and brings about the shock. The substance formed on the introduction of the antigen appears to be of the nature of a precipitin.

Analysis of the anaphylactic and immune reactions by means of the isolated guinea pig lungs, W. H. Manwaring and Y. Kusama (Jour. Immunol., 2 (1917), No. 2, pp. 157-165, fig. 1).—Experimental data submitted show that three essential factors are involved in anaphylactic and immune reactions studied by the perfusion method, viz. cellular hypersensitiveness, or the anaphylactic response of the hypersensitive fixed pulmonary tissues; humoral anaphylaxis, or the chemical response (anaphylatoxin formation) of the anaphylactic blood; and humoral immunity, or the inhibiting or protecting action of the immune blood.

The immune guinea pig, from the data obtained, shows a seemingly paradoxical phenomenon, the coexistence of a fixed cellular hypersensitiveness and a humoral immunity.

The disappearance of agglutinin from the blood of anaphylactic and normal animals, Hilda Hempl (Jour. Immunol., 2 (1917), No. 2, pp. 141-145).—Guinea pigs weighing between 400 and 450 gm, were sensitized with

0.004 cc. of rabbit serum given subcutaneously. Twenty-one days later 0.2 cc. of coli-agglutinating rabbit serum was given intracardially. The sensitized animal displayed moderate anaphylactic symptoms, while the control did not react. Samples of blood were taken from the hearts of both control and experimental animals five minutes and two hours after injection and the agglutinin titer determined. The blood of the sensitized animal showed an agglutinin content higher than that of the control animal five minutes after reinjection, and a lower content than that of the control two hours later.

It is concluded in general that "a foreign serum disappears more quickly from the blood of an animal sensitized to that serum than from that of a normal animal. It disappears more quickly from the blood of highly reacting animals than from that of slightly reacting animals." The individual variation and the need of results from a large number of animals to give definite conclusions is indicated.

The antigenic properties of  $\beta$ -nucleoproteins, H. G. Wells (*Jour. Biol. Chem.*, 28 (1916), No. 1, pp. 11-16).—The results of the study reported are summarized as follows:

The so-called  $\beta$ -nucleoproteins obtained from various tissues by extracting with boiling water possess definite antigenic properties demonstrable by the anaphylaxis reaction. As there are but few known proteins that retain their antigenic capacity after boiling, this observation may indicate something as to the nature of the protein complex of  $\beta$ -nucleoproteins. The proteins of  $\alpha$ -nucleoproteins are, on the contrary, very susceptible to chemical and physical changes.  $\beta$ -Nucleoproteins from beef pancreas, beef spleen, and pig pancreas seem to be similar but not identical, as far as can be determined by the anaphylaxis reaction.

See also a previous note (E. S. R., 32 p. 179).

Transformation of pseudoglobulin into euglobulin, W. N. Berg (U. S. Dept. Agr., Jour. Agr. Research, 8 (1917), No. 12, pp. 449-456).—As indicated by Banzhaf, the author presents evidence of a transformation of pseudoglobulin into euglobulin from data obtained in the concentration of anthrax, diphtheria, and tetanus sera when the sera were heated at 60° C. in the presence of 30 per cent saturated ammonium sulphate. It is noted that the amounts transformed were considerable in some instances, while in one case the amount was so small as to indicate that there was no transformation at all.

The experimental technique used was that described by Eichhorn, Berg, and Kelser (E. S. R., 36, p. 577).

The failure of Homer (E. S. R., 35, p. 680) to observe any transformation of pseudoglobulin into euglobulin is considered by the author as probably due to the use of analytical technique that was not delicate enough to detect such slight transformation, and to errors incidental to the handling of large amounts of serum mixtures.

Weyl's handbook of hygiene: Meat inspection, edited by C. Fraenken (Weyl's Handbuch der Hygiene: Fleishbeschau. Leipsig: Johann Ambrosius Barth, 2. ed., Lieferung 23 (1915), pp. IX-227, figs. 33).—In this part of the 8-volume Handbook of Hygiene meat inspection is dealt with by R. Edelmann. A work by the author on the subject has previously been noted (E. S. R., 35, p. 879).

Are uniform regulations feasible among the different American countries for the prevention of the introduction and dissemination of diseases of animals? A. D. Melvin (Jour. Amer. Vet. Med. Assoc., 50 (1916), No. 3, pp. 361-366).—This is an abstract of a paper in which the author calls attention to the

<sup>&</sup>lt;sup>1</sup> Collected Studies Bur. Lab. Dept. Health N. Y. City, 7 (1912-13), pp. 114-116.

desirability of entering into some kind of cooperation for the exchange of information with regard to contagious diseases of animals, and so far as practicable of adopting uniform regulations for preventing the spread of such diseases. It is pointed out that certain fundamentals should and doubtless could be followed, although the different conditions in different countries will probably make an absolutely uniform set of regulations for all American countries impractical.

Papers on the subject by J. Besnard, chief of the National Veterinary Service, Chile; R. Munoz Jimenez, of Uruguay; and F. Etchegoyen, of Cuba, are included.

Department of veterinary science and bacteriology (Nevada Sta. Rpt. 1916, pp. 38-44, fig. 1).—Investigational work with equine anemia was suspended through the scarcity of material for study in eastern Nevada. Investigations have shown that on some ranches anthrax and hemorrhagic septicemia occur simultaneously, evidence of double infection having been found in two animals.

Work on the separation of the active principle of hog-cholera serum by fractional precipitation is noted as having been successful.

Continuing the work on contagious epithelioma (E. S. R., 35, p. 885), results were obtained which appeared to indicate that the immunity conferred by vaccination without subsequent exposure is of comparatively brief duration. Experiments are being conducted to determine the duration of the immunity conferred by vaccination and that acquired through a natural attack of the disease. It is indicated, however, that too much dependence should not be placed upon vaccination as a preventive measure when exposure does not follow within a brief period of time. An attempt has been made to improve the vaccine by eliminating other bacteria in order to prevent secondary infections. Some experiments are reported in which the vaccine treatment was only moderately successful. The lesions in these birds were characteristic but the symptoms were chiefly catarrhal. A careful bacteriological study showed that the principal cause of the disease was a mixed bacterial infection. indicated that while the experiments are far from conclusive they emphasize the need of further study of secondary bacterial infections, and that the vaccine must probably be of a mixed type rather than absolutely free from other organisms as attempted in the improved technique for its preparation.

Experiments in the immunization of fowls affected with chicken cholera by vaccination followed by inoculation to determine the degree of immunity conferred by the intramuscular inoculation of fully virulent cultures were not successful. It is noted, however, that the clinical results indicate that a degree of immunity sufficient to protect birds against a natural infection is thus conferred. It is deemed probable that the method will eventually prove satisfactory from a clinical point of view, even if the birds treated are unable to resist artificial infection.

Annual report on the Punjab Veterinary College, Civil Veterinary Department, Punjab, and the Government Cattle Farm, Hissar, for the year 1915-16, H. T. Pease, J. Farmer, and R. Branford (Ann. Rpt. Punjab Vet. Col. and Civ. Vet. Dept., 1915-16, pp. II+2+17+XVII).—The usual annual report (E. S. R., 35, p. 483).

Complement fixation in abortions of women, with special reference to the Bacillus abortus and the B. abortivo-equinus, P. F. Williams and J. A. Kolmer (Amer. Jour. Obstet., 75 (1917), No. 2, pp. 193-203).—Complement fixation reactions with polyvalent antigens of B. abortus (Bang) and B. abortivo-equinus and the sera of 50 women aborting in the early months of pregnancy yielded negative results. These organisms were thus apparently not etiological factors in the cases reported.

It is indicated that "since the bacillus of epidemic abortion of cows has been found in milk it is advisable to subject aborting cows to rigid bacteriological and immunological tests for the bacilli before permitting the distribution and consumption of their milk, although it has not been definitely proved that the *B. abortus* is capable of producing abortion in women."

The specific and nonspecific action of rabbit blood serum in the complement-fixation test, I. F. Huddleson (Jour. Immunol., 2 (1917), No. 2, pp. 147-156).—Experiments by the author at the Michigan Experiment Station, to determine whether rabbits would become infected and show Bacillus abortus antibodies in their blood as a result of ingesting milk reacting positively to the agglutination and complement-fixation tests, are reported in detailed tabular form and briefly discussed.

It is concluded that the data do not furnish sufficient evidence to condemn naturally infected milk as dangerous to rabbits by ingestion, since it shows no pathogenic action and no antigenic action. A nonspecific absorption of complement was found to take place in the presence of inactivated rabbit blood serum and a bacterial antigen of *B. abortus*. No explanation of this nonspecific peculiarity of rabbit blood serum is offered.

Resistance of the anthrax bacillus to the action of sodium chlorid solution, J. B. Bordoll (Rev. Hig. y Sanidad Vet. [Spain], 6 (1917), No. 10, pp. 747-751).—Experimental data are submitted which show that anthrax bacilli are not affected by a 10 per cent solution of sodium chlorid, even when in contact with the solution for more than a month. Guinea pigs injected with a suspension of the organisms which had been in contact with the sodium chlorid solution developed symptoms and died in two days with anthrax.

Human anthrax.—Report of an outbreak among tannery workers, W. H. Brown and C. E. Simpson (Jour. Amer. Med. Assoc., 68 (1917), No. 8, pp. 608, 609).—Twenty-five cases of human anthrax which were reported within a period of four months are noted. The clinical histories of twenty of these cases which appeared to have been infected from a common source, namely, three tanneries located in adjoining towns, are given in tabular form.

The data are briefly discussed and recommendations for the control and treatment of the disease submitted.

Report on foot-and-mouth disease from 1912-1916, P. VAN HOEK (Dept. Landb. Nijv. en Handel [Netherlands], Verslag. en Meded. Dir. Landb., No. 4 (1916), pp. 165, pls. 19).—This is a detailed report of the occurrence of and control work with foot-and-mouth disease in the Netherlands from 1912 to 1916 and in other countries since 1911.

Second report of the special committee for the detection of glanders, E. B. ACKERMAN ET AL. (Jour. Amer. Vet. Med. Assoc., 50 (1917), No. 6, pp. 747-757).—This report, by a committee of the American Veterinary Medical Association, considers the cause, susceptibility, period of incubation, modes of infection, symptoms, and the various diagnostic tests for glanders and recommends in general that uniform measures for the control and eradication of the disease by the sanitary officers of various States and Provinces be adopted. See also a previous note (E. S. R., 29, p. 499).

Rinderpest in swine, with experiments upon transmission from cattle and carabao to swine and vice versa, W. H. BOYNTON (Philippine Agr. Rev. [English Ed.], 9 (1916), No. 4, pp. 288-336, pls. 2, figs. 10).—The data submitted show that cattle, carabao, and pigs vary but slightly in susceptibility to rinderpest. It appears that the disease can be transmitted practically as readily from one type of animal to the other as among their individual kind.

The treatment of tetanus with cicutin hydrobromid, Rocton (Rec. Méd. Vét., 92 (1916), No. 23, pp. 684-686).—A case is reported in which the injection

of cicutin hydrobromid into a mare which had already manifested general symptoms of tetanus yielded excellent results.

A contribution to the ophthalmic tuberculin test for the diagnosis of bovine tuberculosis, A. M. Bergman (*Ztschr. Infektionskrank. u. Hyg. Haustiere, 17* (1915), No. 1-2, pp. 87-67, pls. 3).—Tabulated experimental data are reported and discussed.

A tuberculin consisting of 92 per cent of a bovine strain and 8 per cent of a human strain with 40 per cent glycerin was found to yield excellent results. Of 107 animals tested, 87 were tuberculous and 20 nontuberculous. Of the tuberculous animals, 70 reacted positively, 11 were doubtful, and 6 negative. Of the 20 nontuberculous animals, one reacted positively. A second test on the same eye yielded identical results. From the results thus obtained the ophthalmic test is considered to be the most preferable diagnostic test, especially in cases where the animals have been previously sensitized. In the first tuberculin test a sympathetic reaction in the untreated eye was obtained in about 4 per cent of the positive reactions.

A previous sensitization is considered to be of value not only in yielding a more distinct second reaction but also in bringing about an earlier response after instillation of the tuberculin. Repeated instillations of tuberculin at intervals of from one to three days were found to cause a decrease in susceptibility after four instillations. The reaction was evident very early, but also disappeared early, in some cases five hours after the instillation. The ability of the eye to become accustomed to repeated treatment of tuberculin is considered not to be of any practical significance.

Bovine tuberculosis and milk for children, G. Regnér (Deut. Vrtljschr. Öffentl. Gsndhtspflege, 47 (1915), No. 1; abs. in Internat. Centbl. Gesam. Tuberkulose Forsch., 10 (1916), No. 6, p. 166).—The author concludes that human tuberculosis is transmitted chiefly from individual to individual, but the disease may also be transmitted by bovines with open tuberculosis, especially udder infections. In such cases milk is the carrier of the infection, and the infection in most cases takes place in childhood. In a campaign against the disease measures against the transmission of the disease from individual to individual must be devised and all possibilities of infection from bovine sources eliminated, Only milk from tuberculosis-free animals should be used for children. The usual hygienic measures in connection with the use of milk must also be strictly observed.

Box elder poisoning, H. G. Bond (Vet. Alumni Quart. [Ohio State Univ.], 4 (1916), No. 3, pp. 111, 112).—This is a report of the poisoning of cows through feeding on the leaves and seed pods of box elder, which resulted fatally in three of the four animals affected.

Malignant catarrhal fever of cattle in Kansas, L. W. Goss (Vet. Alumni Quart. [Ohio State Univ.], 4 (1916), No. 1, pp. 4-6).—This reports upon studies made of cases of this disease during an outbreak which took place in the fall of 1916.

Bovine onchocerciasis in South America, Piettre (Bul. Soc. Cent. Méd. Vét., 92 (1916), No. 14, pp. 202, 203).—It is stated that an Onchocerca which resembles O. gibsoni, although differing to some extent, has been found to occur frequently in cattle slaughtered in South America. At the Frigorifico La Negra in Argentina 70 per cent of the cattle show extensive lesions on the cervical ligament and 25 per cent localizations on the external face of the great trochanter. At the Frigorifico Uruguaya in Uruguay 90 per cent show cervical lesions and 18 per cent lesions on the trochanter. The localization of this Onchocerca is quite different from the type occurring in France.

The parasite is longer than the European form, females reaching 70 cm. in length, and the lesions are more serious than those produced by the French form. The extensive congestion may give rise to the formation of large pockets in the inflamed connective tissue and frequently to encysted purulent collections.

Bovine sarcosporidiosis, E. E. Franco and I. Borges (Arq. Inst. Bact. Camara Pestana, 4 (1916), No. 3, pp. 269-289, pls. 11).—Six cases of this affection in cattle from the Province of Alemtejo, Portugal, were found to be caused by a species belonging to the new genus Besnoitia, namely, B. besnoiti. The lesions in the form of spherical yellowish granules from 0.25 to 0.4 mm. in diameter were present, especially in the superficial aponeuroses and in the subcutaneous tissue. In generalized infections they occurred in the connective tissue of all parts of the body, head, trunk, and limbs, but were most numerous on the thighs and flanks. A detailed report is given of microscopical studies.

A list of 12 references to the literature is included.

Vesicular stomatitis in cattle, A. Eichhorn (Amer. Jour. Vet. Med., 12 (1917), No. 3, pp. 162, 170).—An account given by the author at the twentieth annual meeing of the U. S. Live Stock Sanitary Association at Chicago, Ill., in December, 1916, of the recent outbreak of this affection detected at Kansas City. The author found the manifestations in the mouth to resemble those of footand-mouth disease so closely that the differentiation was only possible through inoculation tests.

"The transmission of the disease to horses from cattle and the failure to transmit it to pigs, of course, would practically eliminate foot-and-mouth disease; but other things also substantiate a negative diagnosis as far as foot-and-mouth disease is concerned. Not a single case did we observe with foot lesions, either in the originally infected animals or in the exposed cattle. . . . Temperatures were taken of about 100 animals, and in not a single instance did we observe a temperature over 103° F. . . .

"As far as the etiology of the disease is concerned nothing definite has yet been developed."

An outbreak of vesicular stomatitis, J. R. Mohler (U. S. Dept. Agr., Bur. Anim. Indus. Serv. and Regulatory Announcement 116 (1917), pp. 105-107; Jour. Amer. Vet. Med. Assoc., 50 (1917), No. 6, pp. 667-670).—This is a brief account of the outbreak of vesicular stomatitis that took place during the fall of 1916, a report of which by Eichhorn is noted above.

A note on the preparation and use of agglutinin from beans, M. Dorset and R. R. Henley (Jour. Amer. Vet. Med. Assoc., 50 (1917), No. 6, pp. 699-702).—The following improved procedure for preparing the bean extract used to secure a clear serum in hog-cholera work, as previously noted by the authors (E. S. R., 35, p. 488), is described:

The beans commonly known as the "Wisconsin pea bean" have been found to yield the most satisfactory results. Other varieties may prove satisfactory, but appear to be distinctly lower in agglutinative power. The dry beans should be finely ground, so that about 70 per cent will pass through a 20-mesh sieve.

To 20 gm, of the bean meal 100 cc. of physiological salt solution, containing 0.5 per cent crystallized phenol and heated to 60° C., is added. The mixture is thoroughly stirred and placed for about one hour in a water bath, the temperature of which is maintained at 69 to 70°. When the extraction is completed the entire contents of the flask containing the bean meal is poured into a cheesecloth bag and the residue thoroughly pressed. The liquid obtained, while still hot, is mixed with powdered infusorial earth in the proportion of about 2 gm. to 100 cc. of the extract. The mixture is then poured on a folded filter,

the first runnings returned to the funnel, and again passed through the filter. Before use the materials should be passed through a bacteria-proof filter.

In agglutinating the corpuscles in the defibrinated blood, as previously described, the authors have found the use of a saturated sodium chlorid solution more satisfactory than the use of solid sodium chlorid.

Pseudotuberculosis in swine, caseous adenitis, and visceral pseudotubercles, P. Chaussé (Rec. Méd. Vét., 92 (1916), No. 23, pp. 679-682, fig. 1).—The author reports and discusses five observations and points out that the differentiation of such cases from true tuberculosis is not always an easy one. The characteristics of the nodules form the basis for the differentiation. The cause of the disease has not been determined. The bacillus of Koch, however, was not found in the nodules. The importance of the differentiation of the disease from true tuberculosis is emphasized.

The treatment of surgical foot lesions in the horse with sugar, P. Bimbi (Mod. Zooiatro, Parte Sci., 27 (1916), No. 4, pp. 109-116; abs. in Internat. Inst. Bedeutung des Aneurysma Verminosum Equi. Inaug. Diss., Univ. Bern, 1914. The author reports the treatment of six cases of foot injury in horses with sugar, the results of which confirm those obtained by Bussano, previously noted (E. S. R., 36, p. 178). The use of sugar as a dressing promotes the rapid formation of both the soft and horny tissue of the foot to a greater degree than the other dressings commonly employed.

Notes on the occurrence of equine sporotrichosis in Montana and the "blastomycotic" form of Sporotrichum schencki-beurmanni, K. F. MEYER (Proc. Soc. Expt. Biol. and Med., 14 (1916), No. 1, pp. 23, 24).—The author records the occurrence of sporotrichosis endemically in Montana.

A contribution to the knowledge of the clinical importance of verminous aneurism of the horse, C. J. Folmer (Beitrag zur Kenntnis der Klinischen Bedeutung des Aneurysma Verminosum Equi. Inaug. Diss., Univ. Bern, 1914).—pp. 127+IV, pls. 16).—The author first reviews the literature on the subject in connection with a bibliography of 37 titles which is appended, and then deals with studies made of Sclerostomum bidentatum and its effect upon the horse. Fifteen cases which resulted fatally are reported upon at length.

The larvæ of Gastrophilus equi and G. hæmorrhoidalis and infectious anemia of the horse, F. Favero (Nuovo Ercolani, 21 (1916), Nos. 1, pp. 4-7; 2, pp. 17-21; abs. in Rev. Appl. Ent., Ser. B, 5 (1917), No. 2, p. 27).—The author reports upon work the results of which he considers to disprove the findings of the Seyderhelms, previously noted (E. S. R., 35, p. 80), as regards the importance of oestrid larvæ in the etiology of infectious anemia of the horse.

A synoptical key to the adult teniod cestodes of the dog. cat, and some related carnivores, M. C. Hall (Jour. Amer. Vet. Med. Assoc., 50 (1916), No. 3, pp. 356-360).

The value of post-mortem examinations, W. C. Thompson (New Jersey Stas. Hints to Poultrymen, 5 (1916), No. 3, pp. 4).—In addition to brief directions for the examination of sick and dead birds, this contains a chart showing causes, symptoms, and prevention and treatment of the more common diseases of poultry.

A comparative study of Bacterium pullorum and B. sanguinarium, L. F. Rettger and S. A. Koser (Jour. Med. Research, 35 (1917), No. 3, pp. 443-458).—
This is a report of a systematic study made with a view to determining the possible identity or exact relationship of the organisms of bacillary white diarrhea and fowl typhoid.

"Despite the several characters which the two organisms have in common, and particularly the serological reactions, B. pullorum and B. sanguinarium con-

stitute two separate and distinct types, and each bears a specific relationship to the disease with which it has been associated in the past, namely, bacillary white diarrhea or fowl typhoid.

"B. pullorum differs from B. sanguinarium in several important respects, aside from morphology. Dextrin, maltose, and dulcite are attacked by the latter with the production of acid, but no gas. B. pullorum, on the other hand, produces no visible change in media containing these agents except slight alkali production. B. pullorum acts upon dextrose and mannite with the evolution of appreciable amounts of gas, while the fowl typhoid bacillus, whether recently isolated or artificially cultivated for many years, does not produce gas in any of the carbohydrate media. Furthermore, prolonged cultivation of B. pullorum in the laboratory does not cause this organism to lose its power of producing gas in dextrose and mannite broth.

"The methyl red test applied to cultures grown in one per cent maltose bouillon was found to furnish a practical method of distinguishing between the two types of bacteria, B. sanguinarium being methyl red positive and B. pullorum negative.

"While both organisms are pathogenic to fowls of all ages in experimental inoculation, *B. pullorum* manifests itself only as the cause of natural epidemic infection in young chicks. On the other hand, *B. sanguinarium* attacks fowls of different ages, although it is of relatively little, if indeed any, significance as the cause of epidemic disease in very young chicks."

Fowl cholera and other hemorrhagic septicemia immunization experiments, B. GALLAGHER (Jour. Amer. Vet. Med. Assoc., 50 (1917), No. 6, pp. 708-728).—Tabulated experimental immunization data are reported and discussed.

In the experiments an attempt was made to produce immunity to hemorrhagic septicemia by employing as the immunizing agent living organisms of a strain of fowl cholera bacilli nonvirulent for fowls. In one case a mixture of killed organisms of both virulent and nonvirulent strains of fowl cholera bacilli was used. Fowls, rabbits, guinea pigs, and white rats were selected for test animals, and virulent strains of Bacillus avisepticus, B. bovisepticus, B. suisepticus, and B. ovisepticus were used for determining the degree of resistance required.

It is concluded in general that no noticeable resistance is conferred on fowls by the use of killed fowl cholera bacilli as immunizing agents. One strain of fowl cholera organisms conferred a marked resistance to a highly virulent strain of the same bacillus. The immunity, however, was found not to be absolute, since dilutions of from 0.01 to 1 cc. of a virulent culture are usually fatal in fowls, rabbits, and guinea pigs. The same strain also conferred a fair degree of immunity on rabbits against certain strains of B. bovisepticus and complete immunity to a virulent strain of B. suisepticus.

It is indicated that "there is an unknown factor at work in natural fowl cholera outbreaks, since such outbreaks, if due to the fowl cholera bacillus alone, would be easily produced by feeding a virulent culture to susceptible birds. We have failed to produce any symptoms of cholera by feeding several highly virulent strains of fowl cholera organisms."

Epithelioma contagiosum of quail, B. GALLAGHEB (Jour. Amer. Vet. Med. Assoc., 50 (1916), No. 3, pp. 366-369).—The author reports upon an outbreak of bird pox or avian diphtheria at Kansas City among quail received from Mexico during January, 1916, principally for the purpose of stocking game preserves. Eighty-five per cent of some 400 birds under observation succumbed in a period of five weeks. It is stated that there was no indication of the disease during the ten days that the birds were held in quarantine at a point on the border.

### RURAL ENGINEERING.

Fifteenth annual report of the Reclamation Service, 1915-16, A. P. Davis (Ann. Rpt. Reclamation Serv. [U. S.], 15 (1916), pp. 806, fig. 1).—This report relates in particular to the work completed and in progress during the fiscal year ended June 30, 1916, but in addition contains a brief history of construction and engineering features from the beginning of the enterprise in order that its methods, progress, and results may be more readily understood.

Seventh biennial report of the State engineer to the governor of North Dakota for the biennial period ending June 30, 1916, J. W. Bliss (Bien. Rpt. State Engin. N. Dak., 7 (1915-16), pp. 162, pls. 26).—This report of work and expenditures includes data on roads and bridges, measurements of flow of streams of the State, and mining.

Surface water supply of Pacific slope basins in California, 1914 (U. S. Geol. Survey, Water-Supply Paper 391 (1917), pp. 9-334+XXXVI, pls. 2).—
This report, prepared in cooperation with the State of California, contains the results of measurements of flow made on Pacific coast drainage basins in California, together with a list of gauging stations and publications relating to water resources.

Surface water supply of Missouri River Basin, 1914 (U. S. Geol. Survey, Water-Supply Paper 386 (1917), pp. 7-220+XLI, pls. 3).—This report, prepared in cooperation with the States of Colorado, Montana, Nebraska, and South Dakota, presents the results of measurements of flow made on the Missouri River and tributary basins during 1914. Additional sections are included on steam-gauging stations and a list of publications relating to water resources.

Surface water supply of Hudson Bay and upper Mississippi River Basins, 1915 (U. S. Geol. Survey, Water-Supply Paper 405 (1917), pp. 7-215+XXX, pls. 4).—This report, prepared in cooperation with the States of Minnesota, Wisconsin, Iowa, and Illinois, contains the results of measurements of flow made on the Hudson Bay and upper Mississippi drainage basins, together with an appendix of gauging stations and a list of publications relating to water resources.

Second report on the water powers of Alabama, B. M. and M. R. Hall (Geol. Survey Ala. Bul. 17 (1916), pp. 448, pls. 19, figs. 4).—This is a second report on the water powers of Alabama, giving the results of measurements of flow made on the Apalachicola, Choctawhatchee, Escambia, and Mobile River basins, together with river profiles and miscellaneous information.

Profile surveys of rivers in Wisconsin (U. S. Geol. Survey, Water-Supply Paper 417 (1917), pp. 16, pls. 32).—This report, prepared under the direction of W. H. Herron and in cooperation with the State of Wisconsin, describes the general features of natural drainage in Wisconsin and gives plans and profiles resulting from river surveys of the Peshtigo, Chippewa, Black, and Wisconsin River basins.

The economical use of irrigation water, W. L. Powers (Oregon Sta. Bul. 140 (1917), pp. 3-79, figs. 15).—This is a preliminary report of experiments with different volumes of water applied to the chief soils and crops of Oregon during 1915-16, made under a cooperative agreement between the station and the Division of Irrigation Investigations of the U. S. Department of Agriculture. The soils studied ranged from clay loam to coarse sand.

"In Powder Valley, the maximum yield of potatoes was obtained with 7.79 ln., of barley with 16.3 in., and of timothy with 30.55 in. In Wallowa Valley grain yielded highest with 12 in., and alfalfa showed little increase with amounts ranging from 18 to 33 in. In Deschutes Valley grain yielded best with 8 to 17 in., and meadows with 26 in. The most crop per unit of water with

native meadows on central Oregon marshes was obtained with from 10 to 12 in., and the maximum yield with an average of about 18 in. depth an acre. These meadows can be greatly improved in productiveness and a higher efficiency from irrigation water secured by seeding in tame grasses and clovers. On sandy upland at Paisley, the most economical yield was received with from 11.16 to 18 in., and the maximum yield with from 32 to 34 in. The best yield on black sage land in Harney Valley was secured from 6 in. on grain, 8 in. on peas, and 18 in. on alfalfa. In Goose Lake Valley the depth giving maximum yield was 7.5 in. for potatoes, 9 to 16 in. for grain, and 18 in. for alfalfa. In Rogue River Valley 10 in. depth gave the maximum yield of sugar beets, and 6 in. the maximum yield of corn." Results secured in the Willamette Valley from several crops with different amounts of water and the effect of crop rotation and manure in lowering the amount of water required are also reported. "A close relation was found between irrigation, fluctuations in the water table, the substrata, and concentration of alkali on different flat areas."

With reference to the effect of soil texture on the economical use of irrigation water, it was found that "the coarser soils generally have a low water requirement and a comparatively low amount of surface area, pore space, organic matter, and are apt to be medium in fertility. The light, frequent irrigations required on these soils necessitate more waste and it is impracticable to use as small an amount of water on these soils as on the soils of finer texture.

"The kind of crop affects the amount of water required. Alfalfa and other meadow crops are requiring relatively large amounts of water, grain and field peas but medium amounts, and cultivated crops, such as potatoes, still less.

"The altitude and accompanying climatic conditions affect the irrigation requirements. . . . In general for the same soils and crops where 3 ft. depth is needed per season up to 2,000 ft. elevation, 2 ft. is a reasonable amount at 3,000 ft. elevation, and 1.5 ft. for each season is a reasonable amount for elevation of 4,000 ft. or more. Drying or other effects of the weather are intensified at the lower altitudes.

"Soil fertility is one of the most important factors affecting irrigation requirements. . . . Frequently, applying the simple fertilizer needed has saved from a quarter to one-half the total irrigation or doubled the returns for each unit of water where fertilizer was applied. This is especially true on the lighter types of soil.

"The time of irrigation affects greatly the efficiency of the water applied, since irrigation . . . is worth more when applied just at the right time. . . . The amount applied at each irrigation will affect the economical use of water or irrigation requirement. . . . Coarse-textured soils or those with gravelly substrata should have a distribution system that will permit or supply comparatively light and frequent applications which can be retained in the soil without percolation loss. The frequency of irrigation is related to the time and amount for each irrigation. Irrigation should only be applied when the moisture content drops to near the wilting point for the particular soil and crop, and in sufficient amount to fill it up to the excess point in all cases except where flood irrigation in the early spring is necessary to retain as much water as possible in the soil reservoir. This would be true in the absence of artificial storage for summer irrigation. . . .

"The head and length of run should be such that the plat irrigated can be covered by the time the irrigation has wet up the root zone of the crops. A high head forces over the land rapidly and is necessary in flood irrigation or in irrigating loose soils. The longer length of run gives more time for soaking during irrigation on the heavier textured soils. Longer runs can be used on more sloping land and shorter runs with a higher head should be used

on the flatter lands in order to cover the land without waste.... It is important for the irrigated farm to have a moderate proportion of cultivated crops.... Small, direct ditches which carry the water to the point of application will save water as compared with broad, shallow ones, which expose the water to evaporation and percolation loss."

A further cooperative study of the relation of proper irrigation to bacterial count is reported by T. D. Beckwith. It was found "that the bacterial counts vary with soil moisture. . . . Irrigation, by increasing the amount of soil moisture, stimulates bacterial growth."

The drainage of irrigated shale land, D. G. MILLER and L. T. JESSUP (U. S. Dept. Agr. Bul. 502 (1917), pp. 40, pls. 9, flgs. 12).—This bulletin contains information on the drainage of those irrigated lands of the Rocky Mountain States that are underlain by shale.

"Outcroppings of shale and lands immediately underlain by shale . . . are found in northern New Mexico, in southeastern Arizona, in large areas of Colorado, in the eastern portion of Utah, in the extreme eastern part of Idaho, in Wyoming, Montana, and in the western parts of Nebraska and the Dakotas." Three different ways by which the movement of seepage water takes place in shale are "(1) over the top of the undisturbed and impervious strata, (2) between the layers, and (3) through joints, faults, and cleavage planes. . . . The source of the seepage water is deep percolation, resulting from irrigation and from seepage losses from canals and laterals. . . .

"The drainage of shale lands can not be accomplished by ordinary methods of drainage, due to the movement of the water through the shale under pressure and also to the extreme retentiveness of the overlying adobe soil. The three essential factors for successful drainage of shale lands are (1) proper location of drains, (2) sufficient depth, and (3) relief wells. Drains must be so located as to tap the contributing shale features, such as ridges, points, knolls, etc. . . . The amount of shale reached and the amount of water developed are augmented by increasing the depth of the drains. These depths never should be less than 6 ft., and generally depths of 7 and 8 ft. and greater are essential to success.

"A system of drainage in many of the shales will be incomplete and unsuccessful without relief wells. The area of influence of relief wells is small; this necessitates that they be closely spaced—in many cases 5 or 6 to 100 ft. of trench. The most efficient depth for the wells has been found to range from 6 to 20 ft. below the bottom of the tile drain. The major portion of the water developed by most of the drainage systems in shale comes from the relief wells. A diameter of 2 in. has been found to be sufficient for the relief wells, and in most of the shales they have been installed with the soil auger. Frequently, however, hard strata require the use of a churn drill.

"For trenches in shale ranging from 6 to 7 ft. in depth, and with labor at 25 cts. per hour, unit costs for excavating, laying tile, and back filling, together with the cost of installing the relief wells, have ranged from 12 to 25 cts. per linear foot of trench. This does not include the cost of any material for the drains. The acreage costs of drainage of the lands referred to in this bulletin have ranged from \$13 to \$100 per acre for the area actually affected."

Rural sanitation in the Tropics, M. Watson (London: John Murray. 1915, pp. XVI+320, pls. 45, figs. 2).—This book deals with swamp and soil drainage and oiling as antimalarial measures, tropical water supplies, sewage disposal, and general rural sanitation as practiced in British Malaya, Italy, India, Sumatra, Hongkong, and the Philippine Islands, Panama, British Guiana, and Barbados.

The destruction of mosquitoes and their breeding places and the provision of clean and adequate supplies of drinking water seem to have been the greatest of the problems encountered by the author in his work in tropical rural sanitation.

The treatment of sewage by aeration in the presence of activated sludge, E. Bartow (*Trans. Amer. Inst. Chem. Engin.*, 8 (1915), pp. 119-131, figs. 6).—This is a general review of the experience of the author and others.

Methods of clearing logged-off land, C. H. Shattuck (*Idaho Sta. Bul. 91* (1916), pp. 59, figs. 40).—Tests of methods of clearing logged-off lands in Idaho are reported.

It was found that methods employing explosives cost from \$35 to \$150 per acre and frequently required much leveling. Such methods were found to take out stumps completely, break up hardpan, and bring land into cultivation quickly. On the other hand the cost was found to be prohibitive for the poorer farmers and the fertility of the soil was frequently injured by clay, sand, rock, and gravel brought to the surface.

Charpitting was found to cost from \$10 to \$75 per acre and was one of the cheapest methods, as it required no apparatus. Charpitting was not a success in sandy soil, however, and required constant attention and much labor. Burning from the center of the stump by boring cost about the same as charpitting and required less labor and care. Burning from the center by sawing the stump off and skidding it up generally cost less than charpitting and required less care than charpitting or burning from the center by boring. Another advantage of this method is that the fire is kept going by gravity. The general advantages of burning methods were found to be that little capital and only a small amount of inexpensive apparatus are needed, less leveling is required than by the use of explosives, and much débris is disposed of.

Methods employing hoods on outside charpitting, bored stumps, and sawed off stumps cost slightly more than straight charpitting. Such methods were found to require less work and care after the stump was fired and if a condenser was used part of the by-products could be saved.

Methods employing stump pullers on cracked stumps, small stumps, and on small standing timber generally cost more than charpitting and required more equipment. Less leveling was required, the cost of powder was reduced where stumps were cracked, and fewer snags and roots were left than by burning. Methods employing donkey and traction engines on small trees, small stumps, and cracked stumps generally cost much more than charpitting and required skilled operators and expensive machinery. These methods were found, however, to work rapidly in young standing timber or on small stocks of heavy stumps. Little leveling was required, the cost of powder was reduced, and few snags and stumps were left in the soil. Another advantage was that the stumps were piled, preparatory to burning.

Methods employing pasturage were found to be the cheapest of all methods and the best of all methods where time is not an important factor.

Prevention of the erosion of farm lands by terracing, C. E. RAMSER (U.S. Dept. Agr. Bul. 512 (1917), pp. 40, pls. 9, flgs. 18).—This bulletin is based upon the results of surveys, observation, and a study of terraced fields in the best terraced sections of the country, and deals with terracing as a means of preventing the erosion of hillside land, describing the different types of terraces, pointing out the applicability of each to the various kinds of soil and topography and discussing the principles of terrace design.

"The terraces in use in this country are of two general classes, the bench terrace and the ridge terrace... The disadvantages of the bench terrace are that it can not be crossed by modern farm machinery; the banks can not be cultivated, while each bench must be cultivated as a separate field; weeds and

objectionable grasses which grow on the banks tend to sow the entire field. It is best adapted to slopes too steep to permit the use of any form of cultivated terrace, but it can not be recommended for use on slopes exceeding 20 per cent.

"The narrow-base level-ridge terrace... is cheap to construct and easy to maintain. However, ... considerable land is lost to cultivation and the growth of weeds and grasses on the embankments tends to seed the entire field... Outside of these objections, the narrow-base level-ridge terrace, where heavily sodded, renders satisfactory service on pervious soils and slopes not greater than 8 per cent.

"The broad-base level-ridge terrace... has all the advantages of the latter terrace with the added one that no land is lost to cultivation... It is best adapted to use on open, pervious soils on slopes not exceeding 15 per cent, but under proper conditions of design, construction, and maintenance can be used on any soil and on slopes somewhat greater than 15 per cent...

"The broad-base graded-ridge terrace (the Mangum terrace) . . . not only can be cultivated but it can be crossed at any angle with large farm machinery. Its broad base and flat embankment slopes render it less liable to damage by the flowing water than is the case with the narrow-base type. The grade may be either uniform or variable, but both practice and theory indicate the variable-graded terrace to be superior to the uniform-graded type. The graded terrace is adapted particularly for use on impervious and worn-out soils, and on shallow open soils with an impervious foundation. . . .

"By the selection and proper construction of suitable types of terraces erosion can be controlled on slopes up to 20 per cent or even more. Instances were found where erosion was controlled by the use of terraces on land which had a slope of 30 per cent. However, slopes steeper than 20 per cent usually can be devoted more profitably to grasses or timber than to cultivated crops.

"Of all types of terraces, the use of the broad-base level-ridge terrace is recommended wherever conditions will permit. This type, supplemented with efficient tile drains, offers the most ideal method of preventing soil erosion on any type of soil."

The causes of cracks in cement-concrete pavements, A. T. Goldbeck (West. Engin., 8 (1917), No. 2, pp. 59-62).—The causes of cracking in concrete roads are classified as (1) expansion and contraction due to changes in temperature and moisture content, (2) nonuniform bearing under the slab due to frost action, lack of homogeneity in the sub-base and moisture expansion and shrinkage of the sub-base, and (3) bending resulting from heavy loads and impact.

Tests to determine the amount of friction that can act at the sub-base of a concrete road when the slab expands and contracts, made by sliding 6 in. by 2 ft. by 2 ft. concrete slabs along previously prepared sub-bases, gave the results shown in the following table:

Frictional resistance of concrete on various sub-bases.

Kind of base.	Move- ment.	Force.	Coef- ficient.	Move- ment.	Force.	Coef- ficient.	Move- ment.	Force.	Coef- ficient.
	Inches.	Pounds.		Inches.	Pounds.		Inches.	Pounds.	
Level clay	0.001	480	0.55	0.01	1,130	1.30	0.06	1,800	2.07
Uneven clay	. 001	500	. 57	. 01	1,120	1.29	. 05	1,800	2.07
Loam	.001	300	. 34	. 01	1,030	1.18	. 05	1,800	2.00
Level sand	.001	600	. 69	. 01	1,080	1.24	. 05	1,200	1.32
Hinch gravel	.001	450	. 52	. 01	960	1.10	. 05	1, 100	1.26
inch broken stone	. 001	380	. 44	. 01	800	. 92	. 05	950	1.0
3-inch broken stone		1,060	1.84	. 01	1,550	1.78	. 06	1,900	2.18

In tests of the effects of change in moisture content "specimens were made of 1:2:4 and 1:3:6 concrete of very wet and very dry consistency. Several days after hardening they were immersed in water and extensometer readings were made on them at frequent intervals. As long as they were wet they remained expanded, with a maximum expansion of 0.0001 in. per inch of length. After six months they were removed from the water and allowed to dry in the warm, dry air of the laboratory. They immediately began to contract, reaching an ultimate contraction of 0.0008 in. per inch of length."

Policy and program of Government in road construction under the new Federal Aid Law, L. W. Page (Good Roads, 51 (1917), No. 7, pp. 116-118).—This is a brief discussion of important features of the law.

Good roads and community life in Iowa, J. E. Brindley and J. S. Dodds (Iowa Engin. Expt. Sta. Bul. 39 (1917), pp. 31, pls. 5, figs. 4).—This bulletin presents the results of a study of good roads and community life in five typical counties of Iowa, together with a detailed statistical tabulation of what is termed strictly rural traffic. The points in question were (1) the proper distribution of taxes for the construction and maintenance of roads, including culverts and bridges, (2) the cost of marketing agricultural products under the varying conditions presented by a State like Iowa, and (3) the educational and social, as contrasted with the purely economic, value of properly constructed and well maintained public highways.

It is concluded that "the proper distribution of taxes for roads and bridges in a given State is necessarily determined by topography, density and character of traffic, nature of local and commonwealth government with particular reference to the revenue system of each, the density of population and the distribution of the same both from a rural and urban standpoint, the progress of rural organization service, and numerous other considerations."

A survey of the number of farm homes located on different road systems in the several counties showed "that about four-fifths of all the farmhouses considered are located on secondary or township roads. This fact tends to show why there is opposition to spending a relatively high percentage of the highway budget on a small mileage of main-traveled roads. . . . The house miles even of strictly rural traffic reveal the necessity of relatively greater expenditure on the country road system. In Story, Marion, and Carroll Counties it appears that 12, 15.2, and 15 per cent of the roads carry 27.6, 33.9, and 38.8 per cent. respectively, of the rural traffic as already defined, which means that the density of the traffic on township roads is much less than on the county roads. . . . Approximately four-fifths of the Iowa farmers live on the township road system, and also about one-third of the farmers are directly connected with city roads and need not use the county road system for market hauling. To the former transportation costs are determined largely by the condition of the secondary roads, while to the latter no direct benefit would be obtained from the hard surfacing of what are now classed as primary roads."

Tests of western yellow pine car sills, joists, and small clear pieces, C. W. ZIMMERMAN (U. S. Dept. Agr. Bul. 497 (1917), pp. 16, pls. 2, figs. 4).—Tests of the mechanical properties of western yellow pine, with special reference to its use as a structural material, are reported. The following conclusions are drawn:

"The strength values of structural timbers are influenced considerably by the defects found in them. These values vary according to the grades in the green material, but the increase in strength from air seasoning is not uniform and does not vary with the grades. Seasoning greatly increases the strength of the wood, the increase being greater and more uniform in small, clear sticks

than in structural timbers, owing to the development of defects in the latter. Lowering the moisture content of yellow pine causes it to become more brittle.

"Western yellow pine is a lighter wood than the other western lumber species, weighing approximately 26.9 lbs. per cubic foot, oven dry, in structural sizes. The dry weight of clear wood readily suggests its strength or weakness, but this factor alone can not be depended upon to indicate comparative strength when structural forms of various grades are taken into consideration, owing to the presence of defects which have an important influence on their strength."

A table comparing the strengths of various western species, based on tests of small clear specimens, is given. In addition to the results of tests on western yellow pine there are included average values derived from similar tests on material from five trees from each of four other localities.

A lister attachment for a cotton planter, S. H. Hastings (U. S. Dept. Agr., Bur. Plant Indus. [Circ.], 1917, pp. 3, fig. 1).—This circular describes and diagrammatically illustrates a lister attachment to a cotton planter in the nature of a modified sweep, the purpose of which is to push away the dry surface soil. A hole is drilled through each shoe about half an inch from the top and about 7 in. from the rear. Two pieces of 2 by 4 in. lumber, 17 in. long, with one side beveled so that when the two are placed one on either side of the shoe they will just clear the wheel, complete the attachment.

Mechanical unloading of cane, C. J. Tönjes (Arch. Suikerindus. Nederland. Indië, 24 (1916), No. 39, pp. 1518-1561, pls. 18, figs. 17).—This is a description of the principles of operation and the mechanical details of unloading and conveying machinery and apparatus for sugar cane.

Modern farm buildings, A. Hopkins (New York: Robert M. McBride & Co., 1916, pp. 206, pls. 31, figs. 77).—It is the purpose of this book to give suggestions "for the most approved ways of designing the cow barn, dairy, horse barn, hay barn, sheepcote, piggery, manure pit, chicken house, root cellar, ice house, and other buildings of the farm group, on practical, sanitary, and artistic lines."

Dairy buildings (Bien. Rpt. State Dairy Bur. [Cal.], 11 (1915-16), pp. 16-37, figs. 22).—A number of plans for milking sheds are given.

Community hog houses, J. B. DAVIDSON, J. M. EVVARD, and W. G. KAISER (Iouca Sta. Bul. 166, abridged ed. (1916), pp. 40, figs. 29).—An abridged edition of Bulletin 166, previously noted (E. S. R., 35, p. 587).

Building a self-feeder [for swine], E. W. Lehmann (Missouri Sta. Bul. 144 (1917), pp. 18-22, figs. 4).—Plans and specifications for a one-way and a two-way self-feeder for hogs are given.

### RURAL ECONOMICS.

The country church; an economic and social force, C. J. GALPIN (Wisconsin Sta. Bul. 278 (1917), pp. 48, figs. 16).—The author points out that:

"Farmers go to church in the open country churches in which 95 per cent of the membership are from farm families; in hamlet churches where 75 per cent of the members are from the farm; in village churches where 50 per cent of the members are from the farm; and in small city churches where the farm membership is but 15 per cent. The open country and hamlet churches have the best chance in a farm population that is not shifting about from place to place. A large compact parish, a single church in the parish, and a regular pastor or priest living in the parish are social conditions of strong country and hamlet churches. . . .

"Agriculture is a party to the rural church problem for the reason that in the national struggle to unite farmers into successful producing and business groups the rural parish is a force whose pull is felt by local agriculture. . . . "A joint commission from the national religious bodies could formulate the principles upon which to reparish the rural districts so as to give every farm family a chance to belong to a strong church. . . . Some examples of farmers' churches in Wisconsin [which] show how churches and their religious leaders are cooperating with a progressive agriculture in rural social development" are cited.

A brief account of the life of Rev. John Frederick Oberlin is appended.

Living conditions in rural Alabama, J. B. Hobdy (Montgomery, Ala.: Brown Printing Co., 1915, pp. 27).—The information given in this report was gathered by a questionnaire sent to 402 high-school pupils, and relates to the work of the wife and children on the farm and in the home, and the extent of modern conveniences, recreation, and sanitary conditions.

Wages of farm help [in Iowa] ([Bien.] Rpt. Bur. Labor Statis. Iowa, 17 (1915-16), pp. 119-122).—Statistical data are given showing by counties the average monthly wages paid during the summer and winter months for 1915, with comparative data for earlier years.

[Conditions among rural laborers in Finland in 1901], H. Gebhard (Statis. Undersökn. Soc. Ekon. Förhål. Finland, No. 5 (1916), pp. X+211).—In this report are discussed the conditions of the homes, the amount of land possessed by the laborers, and the number of live stock. Extensive data are included showing conditions in various regions.

Rate sheet essential in long time and short time farm loans, R. L. Bennett (Tex. Agr. Col. Ext. Serv. Bul. B-28 (1916), pp. 8, figs. 2).—The author points out the essentials of safe farming, gives a sample rate sheet, and calls attention to the relation between the cost of securing a loan based upon a single crop system of farming compared with the cost under a diversified system which attempts to produce food and feed for the farm.

The Federal Farm Loan Act, R. J. BULKLEY (Jour. Polit. Econ., 25 (1917), No. 2, pp. 129-147).—The author gives the history of the various bills introduced in Congress regarding rural credit, describes their striking features, and discusses the provisions of the Federal Farm Loan Act as finally passed.

The working of credit banks in the Netherland East Indies, H. C. Alting (Trans. 3. Internat. Cong. Trop. Agr. 1914, vol. 1, pp. 109-124).—The author describes the different types of credit institutions, the organization for promotion and supervision, and the attitude of the native population.

Annual report on the working of cooperative societies in the Bombay Presidency, 1916 (Ann. Rpt. Work. Coop. Socs. Bombay Pres., 1915-16, pp. 6+39+3).—This report continues data previously noted (E. S. R., 35, p. 589).

**A** municipally owned and operated abattoir, E. H. McCuistion (*Texas Dept. Agr. Bul. 51* (1916), pp. 14, figs. 3).—The author discusses the method of organization and operation, and describes the construction and plan of the abattoir, as well as the inspection service.

Market survey of the City of Atlanta, Georgia, J. A. Montgomery (Atlanta, Ga.: State Dept. Agr., 1915, pp. 57, pl. 1).—The author discusses the quantity and sources of products handled, marketing conditions, cold storage facilities, standards in use, and agencies available for improving the marketing of agricultural products.

Report on the storage and handling of wheat in bulk in Victoria (Melbourne: Govt., 1916, pp. 78, pls. 20, figs. 2).—Among the conclusions reached by John S. Metcalf Co., Limited, in their study of the bulk handling of wheat are the following:

"The rail and ocean freights on the bags is an important and unnecessary loss. Any supposed extra value of bagged wheat abroad is more than offset

by the extra cost of handling such wheat at the importing point. . . . It offers no encouragement to the farmer to grow the best wheat possible as would a system offering a premium for quality. . . .

"Unloading farmers' wagons, loading and unloading railway trucks, and loading and unloading of ocean vessels would be very much quicker under the bulk than under the bag system.... The saving in time of loading and unloading vessels should result in lower freight rates, even if any possible extra costs for preparing vessels or for insurance should tentatively be considered operative for a time....

"The present large waste of wheat from weather and vermin damage, leakage, and rebagging can be prevented by the bulk system. . . . The bulk system offers a better method of financing . . ., will provide cheaper means of cleaning wheat, will save the freight on rubbish now shipped abroad, and the cleaned wheat will obtain higher prices in Europe. . . .

"A system built and operated by the Government is recommended, with the farmers adequately represented in its control. Inspection, weighing, elevator operation in general, and marketing, should be under supervision of a grain commission."

Comments of the Victorian Railways Commissioners on the report on the bulk handling system of wheat in Victoria (Melbourne: Govt., 1916, pp. 7).—These comments are made on the report in the abstract given above.

Monthly crop report (U. S. Dept. Agr., Mo. Crop Rpt., 3 (1917), No. 3, pp. 21-28).—In this report are contained the usual data regarding the estimated farm value of important crops and range of prices of agricultural products at important markets. Data are also given concerning the farm stocks on hand March 1 and the shipments out of the counties where grown of wheat, oats, corn, and barley, and concerning farm wages of male labor per month, per day at harvest time, and per day at other than harvest time, with and without board. Special reports are given concerning Florida and California crops, the shortage in 1916 in the world's potato crops, frost damage March 4, 1917, in Texas and California, monthly farm marketings and exports of wheat, the effect of the cold wave February 1 to 6 on truck crops in Florida, and other data.

A special investigation is reported regarding the use of firewood on farms. It was found that the total amount used was 81,875,000 cords valued at \$225,-426,000. The average number of cords per farm was 12.5 and the average value \$34.35.

[Extent of crops grown on reclamation projects] (Ann. Rpt. Reclamation Serv. [U. S.], 15 (1915-16), pp. 681-695).—These pages give data as to the acreage, average yield, and value of crops grown on the individual reclamation projects.

Annual statistics of Chile (An. Estad. Chile, 10 (1913-14), pp. 8+195, pls. 14; 10 (1914-15), pp. 308).—These volumes continue data previously noted (E. S.  $\mathbb{R}_{\bullet}$  32, p. 689), adding data for 1913-14 and 1914-15.

The agricultural situation in the Department of Corrèze [France] before the war, P. Berthault (Ann. Sci. Agron., 4. ser., 5 (1916), Nos. 1-6, pp. 157-206, pl. 1, figs. 12).—After discussing the condition of the soil, climate, means of communication, sizes of farms, and rural population, the author calls attention to the use of land, extent of crops, and live stock production under war conditions.

[Increasing the agricultural production of Italy], S. Lissone (Ann. R. Accad. Agr. Torino, 58 (1915), pp. 77-115).—The author gives the extent of agricultural production from 1909 to 1914 and the number of live stock, and points out the causes for the scarcity of certain agricultural products. He believes that this scarcity is due to the lack of knowledge of the best agricultural

practice and the lack of capital. He advocates the establishment of experimental and agricultural educational institutions, an increase of capital, and a better application of labor.

[Agriculture and live stock in Sweden] (Sveriges Off. Statis., Jordbr. och Boskapsskötsel, 1913, pp. VIII+160).—This report gives by minor subdivisions data as to the area and production of the principal crops, the number of live stock, and the number of agricultural enterprises.

[Agricultural statistics of Norway] (Aarsber. Offentl. Foranst. Landbr. Fremme, 1915, I, pp. 90; 1916, I, pp. 88).—These reports continue the data previously noted (E. S. R., 33, p. 193), adding data for 1915 and 1916.

[Agricultural statistics of Finland, 1910] (Finlands Off. Statis., III, No. 9, pt. 1 (1916), pp. 327).—Statistical data are given for minor subdivisions showing the area devoted to different agricultural purposes, the classification of farms by the area of cultivated land, and the extent of those farms devoted to the principal crops. The number of agricultural machines are given for all farms and for the farms classified by sizes.

# AGRICULTURAL EDUCATION.

[The teaching of rural sociology], D. Sanderson (Amer. Jour. Sociol., 22 (1917), No. 4, pp. 433-460).—The author has gathered information by means of a questionnaire as to the content of the courses of instruction in rural sociology, the relation of the courses to the other departments of the institution, and their extent.

The value of home economics in our schools, Frances Ray (Proc. and Addresses N. C. Teachers' Assembly, 32 (1915), pp. 205-211).—The author discusses the educational, cultural, social, and vocational values of home economics and its correlation with other school subjects.

The school garden as regarded and carried on in the different provinces (Canada Dept. Agr. Pamphlet 4 (1916), pp. 64, figs. 33).—A series of articles on school gardening in Canada, previously noted (E. S. R., 33, p. 897; 34, pp. 92, 93; 35, p. 594).

Proceedings of the [Illinois] high school conference, 1915, edited by H. A. HOLLISTER (Univ. Ill. Bul., 18 (1916), No. 21, pp. 78-95, 173-193).—The following papers presented before the agricultural and domestic science sections of this conference are included: Requirements for University Entrance Units in Agriculture; The Use of the Home Farm as a Laboratory for Secondary School Agriculture; Vocational Opportunities in Scientific Agriculture; The Home Course as Taught in the High School; and Problems in High School Sewing. Reports of the committee on agricultural textbooks and reference libraries and of the executive committee of the domestic science section embodying suggestions for teaching various subjects are also given.

The agricultural section recommended to the faculty of the College of Agriculture of the University of Illinois that schools be credited in agriculture up to four units for specific subjects, such as agronomy, animal husbandry, horticulture, etc., providing the work is approved by the high-school visitor. It was the opinion of the section that instead of the one-year general course in agriculture specific courses of not less than one semester's length in single phases of agricultural work should be given.

Notes on agricultural instruction in Spain, H. Gorbia (Rev. Inst. Agr. Catalán San Isidro, 65 (1916), No. 18, pp. 277+282).—This is a brief survey of the facilities for agricultural instruction in Spain, including The School for Agricultural Engineers in Madrid; the Provincial Higher Agricultural School at Barcelona; schools of agriculture with theoretical and practical instruction,

practical farm schools, the school of viticulture and enology, and the school of aviculture; general argicultural, ampelographical, enological, pomological, sericultural, irrigation, olive culture, enotechnical, rice, seed control, vegetable pathology, dairy, and agricultural machinery testing stations; the acclimatization garden; provincial demonstration and experiment fields and laboratories, and provincial district agricultural experts; the Catalán Agricultural Institute of San Isidro (an agricultural society organized more than 60 years ago), which offers annually courses in agricultural chemistry, etc.; and publications.

The story of corn and the westward migration, E. C. Brooks (Chicago and London: Rand McNally and Co., 1916, pp. IX+308, pl. 1, figs. 114).—This book treats of the struggle of the human race for food; food as a factor in civilization; the origin of corn, and the effect of its discovery on the world's food supply; the opening and settling of the great corn country and connecting it with the world; the economic value of corn; changes in the cultivation, harvesting, and marketing of grain; farmers' demonstration work and the corn-club movement; varieties of corn; and the most important corn products. This is a companion book to The Story of Cotton (E. S. R., 29, p. 738), and may be used with it as a course in elementary economic history for the last year of the grammar school or the first year of the high school.

Vegetable gardening, L. H. Carris and H. F. Tompson (N. J. Dept. Pub. Instr., El. Agr. Leaflet, 4 (1916), pp. 27).—Instructions are given for pursuing the project of vegetable gardening, which may be conducted as (1) school gardening, in which the ground may be used either wholly for the cultivation of one vegetable, as a general kitchen garden, or for individual plats; and (2) individual and partnership home gardening. Correlations with other school subjects and references to literature are suggested.

Productive feeding of farm animals, F. W. Woll (Philadelphia and London: J. B. Lippincott Co., 1916, pp. XII+385, pl. 1, figs. 105).—In this second edition of this text, previously noted (E. S. R., 33, p. 696) a few minor changes and corrections have been made, and a chapter on Feeding Poultry, by J. E. Dougherty, has been added.

Judging farm animals, C. S. Plumb (New York: Orange Judd Co., 1916,  $pp.\ XI+590,\ pl.\ 1,\ figs.\ 299$ ).—The author presents a study of animal form and function in general and of horses, cattle, sheep, and swine in particular. An appendix contains rules governing live-stock judging contests, boys' stock judging contests, the students' contest in judging dairy cattle at the National Dairy Show in 1916, and age classification in the show ring. The volume is intended to serve the stockman but more especially the student.

Dairy farming, C. H. Eckles and G. F. Warren (New York: The Macmillan Co., 1916, pp. XV+309, pl. 1, figs. 78).—This book, which is adapted for use in schools and colleges, is the first of a series of texts to be known as The Farm Series, each of which is to discuss the phases of its subject that are of most importance to the farmer. This text deals with the importance of the dairy industry, breeds of cattle, selection, improvement, management, feeding, and common ailments of dairy cattle, the dairy barn, milk and its products, conditions affecting the development of dairying, systems of farming on dairy farms, methods of renting dairy farms, cost of production and methods of marketing, and other important factors for success in dairy farming. From three to five recitations and two laboratory periods a week are recommended as usually desirable.

A laboratory manual of foods and cookery, EMMA B. MATTESON and ETHEL M. Newlands (New York: The Macmillan Co., 1916, pp. XI+325, figs. 5).—In this laboratory manual a considerable number of experiments are given under each topic to afford a knowledge of the leading characteristics of each kind of

food, furnish a basis for the discussion of the procedures used in cookery, and give a grasp of the principles involved that will enable the student to work without recipes or to develop her own. Thoroughly tested recipes, a considerable number of score cards for judging the finished products, illustrative calculations of nutritive values of typical cooked foods, and references to literature are included.

A rural arithmetic, I. A. Madden and E. A. Turner (Boston: Houghton Mifflin Co., 1916, pp. XV+258, figs. 30).—The problems in this text are based on rural activities, such as the mathematical phases of farm crops, fertilizers, feeding of live stock, household economy, fencing, building and construction, silos, and horticulture. Two chapters are devoted to business forms and farm accounts, and about one-fourth of the book to a systematic review of the fundamental principles of arithmetic. It is intended for the seventh and eighth grades of rural schools and for secondary schools offering courses in agriculture.

The school garden: How to establish it, practical instructions and directions, J. C. Magnan (Min. Agr. Prov. Quebec Bul. 12 (1915), pp. 24, pls. 7, flgs. 6).—This bulletin contains directions for establishing school-garden work and reasons for teaching agriculture in the elementary school.

Gardening for the schools of Saskatchewan (Regina: Dept. Ed., 1915. pp. 41, pls. 12).—This publication discusses the desirability of school gardening instruction, defines horticulture, and gives detailed directions for school-garden work.

# MISCELLANEOUS.

Twenty-ninth Annual Report of Georgia Station, 1916 (Georgia Sta. Rpt. 1916, pp. 31, figs. 6).—This contains the organization list, reports by the president of the board of directors and the acting director of the station on its work during the year, a financial statement for the fiscal year ended June 30, 1916, and two special articles, which, together with the experimental work reported in the acting director's report, are abstracted elsewhere in this issue.

Annual Report of Idaho Station, 1916 (Idaho Sta. Bul. 92 (1916), pp. 71, figs. 9).—This contains the organization list, reports by the director and heads of departments, the experimental features of which are for the most part abstracted elsewhere in this issue, and a financial statement for the main station for the fiscal year ended June 30, 1916, and for the substations for the period from December 1, 1914, to December 31, 1916.

Annual Report of Iowa Station, 1916 (*Iowa Sta. Rpt. 1916*, pp. 36).—This contains the organization list and a report by the director of the work of the station, including a financial statement for the fiscal year ended June 30, 1916. The experimental work recorded is for the most part abstracted elsewhere in this issue.

Annual Report of Nevada Station, 1916 (Nevada Sta. Rpt. 1916, pp. 56, figs. 8).—This contains the organization list, a report of the director on the work of the station, departmental reports, the experimental work in which is for the most part abstracted elsewhere in this issue, a list of the publications of the year, and a financial statement for the fiscal year ended June 30, 1916.

Twenty-seventh Annual Report of New Mexico Station, 1916 (New Mexico Sta. Rpt. 1916, pp. 64, figs. 4).—This contains the organization list, a report of the director on the work, publications, and exchanges of the station, including reports of heads of departments, and a financial statement for the Federal funds for the year ended June 30, 1916. The experimental features are for the most part abstracted elsewhere in this issue.

Report of the Hood River, Oregon, Branch Experiment Station, 1916 (Oregon Sta. Bul. 141 (1917), pp. 56, figs. 10).—A report is given of the work of the year, the experimental features recorded being for the most part abstracted elsewhere in this issue.

Twenty-sixth Annual Report of Washington Station, 1916 (Washington Sta. Bul. 136 (1917), pp. 66, figs. 17).—This contains the organization list, a report on the work and publications of the station during the year, and a financial statement for the fiscal year ended June 30, 1916. The experimental work reported is for the most part abstracted elsewhere in this issue.

Publications of the work of the agricultural experiment station of the Rhode Island State College (Rhode Island Sta. Bul. 169, Sup. (1917), pp. VIII).—Lists are given of the annual reports and bulletins of the station since its establishment, and of contributions by members of its staff to scientific journals since 1909.

Monthly bulletin of the Western Washington Substation (Washington Sta., West. Wash. Sta., Mo. Bul., 4 (1917), No. 12, pp. 20, figs. 2; 5 (1917), No. 1, pp. 16).—These numbers contain brief articles on the following subjects:

Vol. 4, No. 12.—Peas and Vetches in Western Washington, by E. B. Stookey; Care and Management of Baby Chicks, by Mr. and Mrs. George R. Shoup; Spraying Program for 1917, by A. Frank; and Tanning Mole Skins.

Vol. 5, No. 1.—Poisoning by Water Hemlock, by S. B. Nelson; Benefits from Cow-testing Associations, by O. E. Gibson; Soiling Crops, by H. L. Blanchard; Burning Stumps in Place, by I. D. Charlton; Cereals in Western Washington, by E. B. Stookey; The Spring Moult, by Mrs. Geo. R. Shoup; and Plant Clean Potato Seed, by A. Frank.

# NOTES.

Alabama Stations.—Frank R. Curtis, county agent of Marengo County, has been appointed director of the Canebrake Station. L. H. Moore, the former director, is to continue as assistant director, and Director J. F. Duggar of the College Station will act as advisory director in the experimental work.

Arkansas University and Station.—J. Lee Hewitt, head of the department of plant pathology since 1909, resigned June 1 to take up State inspection work for the newly established State plant board. Dr. J. A. Elliott, associate plant pathologist of the Delaware College and Station, has been appointed to succeed him, beginning July 1. G. W. Hervey has resigned as assistant in animal husbandry, and has been succeeded by S. R. Stout.

Connecticut College.—The college closed May 11, as only 20 of the 200 students registered still remained, the others having engaged in various forms of military and agricultural service.

Purdue University and Station.—C. G. Woodbury, horticulturist, has been appointed director of the station beginning September 1. J. D. Harper, assistant in crops in the extension work, has become county agent for Laporte County.

Maine University.—By May 9, 420 students had withdrawn from the institution for war service, about half for work on farms.

Maryland College.—Special short courses in practical farm work are being offered to women, beginning June 4.

Massachusetts College and Station.—Despite the general policy of stringent economy, the State legislature appropriated \$40,000 to enlarge the power plant, \$33,000 additional for new equipment, \$17,500 additional for running expenses to meet the increased costs of labor and supplies, and \$10,000 for maintenance and improvement of the market garden substation at Lexington.

Because of the war conditions, the elaborate celebration of the fiftieth anniversary of the opening of the college, planned for next October, has been postponed.

Missouri University.—University students who enlisted for national service in connection with the war have been given credit for the current semester with a grade based on the quality of the work being done at the time of enlistment. More than 550 students have availed themselves of this opportunity for service. The university has also placed at the disposal of the Government any technical equipment and apparatus that can be of use. Members of the teaching staff who take up work with the Government are to be granted leave of absence during the period of such service.

Recent appointments include L. L. Alexander as extension assistant in farm crops, Winona Windsor as extension assistant in home economics, W. W. Langston as county agent for Butler County, and E. J. Trosper as district agricultural agent for northeastern Missouri. R. A. Kinnaird has been promoted from extension instructor to extension assistant professor of soils. Charles G. Carpenter, assistant in horticulture, has resigned.

Nevada University and Station.—The State has organized a committee on food resources, of which Dean C. S. Knight of the College of Agriculture is chairman and Director S. B. Doten of the station, secretary.

New Hampshire College.—By May 14 about 230 students had left to work on farms.

New Jersey College and Stations.—Recent appointments include William H. Hamilton as assistant State leader in farm demonstration, R. F. Poole as research assistant in plant pathology, and Louis Schwartz, as assistant chemist. Frank O. Fitts, assistant chemist, and Miss Nevada S. Evans, assistant seed analyst, have resigned.

Cornell University and Station.—Dr. A. W. Gilbert, professor of plant breeding, who has been on leave of absence for graduate work in rural economics at Harvard University, has resigned and accepted an appointment with the Boston Chamber of Commerce. Donald K. Tressler, assistant in agricultural chemistry, has resigned to accept a position with the Bureau of Soils of the U. S. Department of Agriculture.

Ohio State University and Station.—Following a faculty ruling permitting students to withdraw from the university with full credit to take positions on farms, approximately 600 students have left for this purpose. Of these 414 are from the college of agriculture and the remainder chiefly from the arts college.

An additional experiment farm is to be located in Belmont County in the near future.

Oregon College and Station.—The forty-eighth annual commencement was held June 4, 281 graduates receiving degrees. There were also 101 absent on military or civil duty connected with the war, who were graduated in absentia.

A grain grading course for farmers and wheat dealers was held under the auspices of the farm crops department June 7 to 14. The purpose was to acquaint growers and others interested with the new Federal grain standardization rules and afford training in classifying and grading northwestern grains.

E. L. Westover, a graduate of the Kansas College with experience in the organization of breeding associations in Minnesota and Wisconsin, has been appointed cooperative extension specialist in dairy husbandry, vice W. A. Barr resigned to become a county agent in Arizona. D. E. Richards, foreman of the college live stock farm, has been appointed instructor in animal husbandry. R. I. Scoville, of the dairy department, and Geo. F. Moznette, of the department of entomology, have resigned to accept appointments with the U. S. Department of Agriculture. John T. Bregger of the Michigan College, and Frank H. Lathrop, of the Ohio State University, have been appointed teaching fellow in botany and research assistant in entomology, respectively. It is reported that over 60 members of the faculty have resigned to accept positions in other institutions or in the Federal service during the present college year.

Pennsylvania College and Station.—Harold Williamson, herdsman for three years, was killed in France recently while serving with a Canadian regiment. P. S. Baker, assistant agronomist, resigned April 1; A. A. Hansen, instructor in botany, May 1; G. A. Meckstroth, assistant in botany, June 1; and I. J. Bibby, instructor in dairy husbandry, June 21. Recent appointments effective July 1 include C. G. McBride as assistant professor of agricultural extension, C. F. Preston as assistant professor of farm organization extension, and Miss Edna B. MacNaughton and Miss Aurelia B. Potts, as instructors in home economics extension. J. S. Owens has been appointed assistant in experimental agronomy, effective June 13.

Porto Rico Insular Station.—On March 3, under the provisions of the new organic act for Porto Rico, the Board of Commissioners of Agriculture was dissolved and the management of the station passed into the hands of the Department of Agriculture and Labor, of which Manuel Camuñas is commissioner.

Rhode Island College.—By May 8 approximately half the students had left the college for agricultural work. The college is cultivating about 300 acres of additional land.

South Dakota Station.—As a result of experiments conducted by the department of chemistry during the past 20 years, it is expected that sugar beet factories will soon be established in both the eastern and the western part of the State. Information from western South Dakota, where sugar beets are being raised on a large scale, shows that the price of land has greatly increased. The loss of so many sugar factories in Belgium and France is reported as stimulating efforts to produce more sugar in this country.

In an experiment to determine the best time to cut corn for the silo, steers fed an exclusive ration of the silage, cut at four different periods, gained during 148 days over 2 lbs. per head daily. In an experiment in breeding sheep, the wool from half-blood Siberians or half-blood fat rump sheep brought as much in the market as wool from the pure-bred Down breeds.

Texas College and Station.—Provision has been made by the legislature for establishing a third junior agricultural college, to be known as the Northeast Texas Agricultural College. An appropriation of \$250,000 has been made for its establishment and maintenance. The board of directors of the State A. and M. College is given control over the institution.

State appropriations have also been made for the station and substations aggregating \$225,095.34 for the year beginning September 1, and \$181,270.40 for the following year.

Utah College and Station.—Recent appointments include Dr. M. C. Merrill as professor of horticulture and horticulturist, Bervard Nichols as assistant in plant pathology, J. H. Wittwer and Horace Argyle as agricultural demonstrators for Uinta and San Juan counties respectively, and L. M. Price as assistant demonstrator for Weber County. George Stewart has been made assistant professor of agronomy in the college and assistant agronomist of the station, and H. R. Hagan, assistant professor of zoology and entomology in the college and associate entomologist in the station. W. E. Goodspeed, assistant horticulturist, has resigned to engage in commercial work.

**Vermont University.**—Following a general exodus for war service, only about **15** students were left by May **14** in the agricultural courses.

Virginia Station.—A. A. Ingham, assistant horticulturist, died June 13.

Washington Station.—Geo. Severance, agriculturist, was appointed acting director May 1. C. A. Thompson has been appointed assistant in soils and assigned to the dry land substation at Lind. O. E. Barbee has been appointed assistant in farm crops. C. B. Sprague resigned May 1 as assistant horticulturist to accept the position of county agriculturist of Kitsap County.

Wisconsin University and Station.—Dr. E. V. McCullom, professor of agricultural chemistry and agricultural chemist, has been appointed professor of biological chemistry at the new school of hygiene and public health at the Johns Hopkins University. Miss Nina Simmonds and Walter Pitz, assistants, have also accepted appointments in the same institution.

The recent death is noted of Carl D. Livingston, assistant professor of agricultural engineering. Professor Livingston was a 1914 graduate of the University of Washington, with a year's graduate work in agricultural engineering at the Ohio State University. His service at the University of Wisconsin began in 1915 at the forest products research laboratory. His work in the college of agriculture had dealt especially with tests of land clearing methods and apparatus.

Wyoming University.—Dean H. G. Knight has been made chairman of the State Council for National Defense, organized April 17. Every county in the

State has a county council, and the increased land placed under plow is estimated at about 20 per cent.

Philipppine College of Agriculture.—A bill appropriating 125,000 pesos (\$62,500) for the establishment of an experiment station in connection with the college was passed by the House of Representatives at its last session, but reached the Senate too late for action. An appropriation was made for the completion of a series of students' houses near the new site of the forest school.

Beginning with April, 1918, the requirements for entrance to the 6-year course of the college of agriculture have been raised to include two years of high-school work. New forestry courses leading to a degree in forestry have also been announced.

Changes in Canadian Agricultural Institutions.—Dr. C. Gordon Hewitt has been appointed by the Canadian Government consulting zoologist in addition to his previous duties as Dominion entomologist and chief of the entomological branch of the Department of Agriculture. His new duties will be of an advisory nature in matters relating to the protection of birds and mammals and the treatment of noxious species.

- G. H. Cutler, professor of cereal husbandry in the University of Saskatchewan, has been appointed to a corresponding position in the department of field husbandry of the University of Alberta, beginning July 1.
- F. S. Jacobs, professor of animal husbandry at the Manitoba Agricultural College, has resigned to take up farming in Alberta.

Necrology.—Professor Emil von Behring, widely known for his studies in bacteriology and immunology, died April 5. Professor von Behring was born in 1854 and received his professional education at the Army Medical College, Berlin, obtaining the doctor's degree in 1878. In 1898 he was appointed assistant in the Institute of Hygiene at Berlin and in 1891 in Koch's Institute for Infectious Diseases. He was made professor in 1894 and appointed to the chair of hygiene in the University of Halle, and in the following year he became professor and director of the Institute of Hygiene at Marburg. He was best known as the discoverer of diphtheria antitoxin, but had also worked extensively on tuberculosis and other diseases.

T. Wilson, inspector of Indian orchards in the entomological branch of the Canadian Department of Agriculture, was fatally burned in a hotel in British Columbia, March 6. He had been notably successful in stimulating interest in fruit growing and horticulture among the Indians, as well as in promoting entomological and botanical work in the region.

Lieut. H. N. Thompson, weeds and seeds commissioner in the Saskatchewan Department of Agriculture, was killed in action at Vimy Ridge, France. J. A. P. Arden, of the Sidney, B. C., substation, has also been killed in action.

Miscellaneous.—M. D. Butler and B. C. Sibley, of the Oregon Agricultural College, have been appointed extension specialists in the Nicaragua Department of Agriculture. Their work is to consist mainly of field demonstrations and the introduction of promising crops.

Nature announces that publication of the Kew Bulletin has been suspended under an order deferring, because of the shortage of paper and other considerations, the issue of all Government publications not deemed essential.

The Agricultural Institute at Alnarp, Sweden, is planning to erect a building to cost about \$20,000, for studies in heredity under the direction of H. Nilsson Ehle, recently appointed professor at Lund.

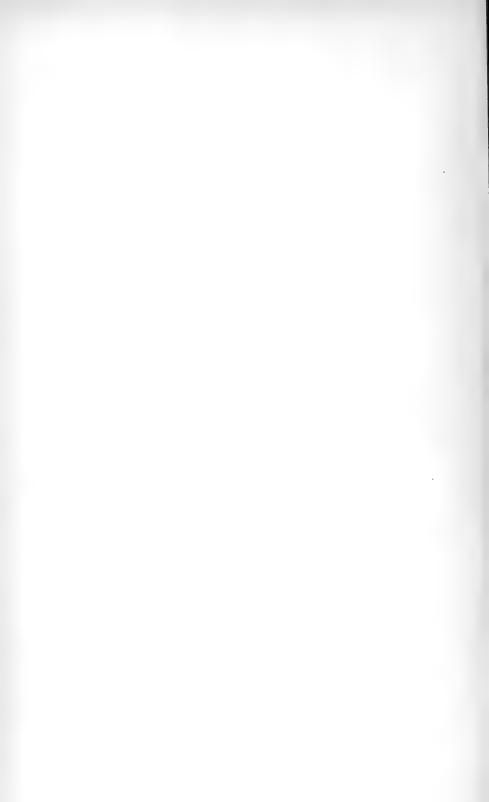

According to a recent number of School and Society, Victor E. Rector has been elected professor of agriculture at the University of South Carolina.

## EXPERIMENT STATION RECORD.

Vol. 37.

August, 1917.

No. 2.

The responsibilities of the administrative officers of our agricultural institutions have been brought out in a new light by the entrance of the country into war. The new and unprecedented demands have imposed a heavy tax upon the organizations of these institutions and tested the provision which had been made for handling the various phases of the agricultural work. The experience has developed the broad field which these administrative officers are attempting to cover through their own personal efforts in a manner to raise anew the question whether sufficient provision has generally been made in the administrative machinery to insure strength and elasticity and bring the best results.

Manifestly no organization could fully provide against such an unusual contingency, but the more complete the organization the better the added strain may be distributed. The special demand upon these institutions has just begun, and their opportunity will not close with the war. Hence the question of strengthening the organization where necessary is a pertinent one at this time.

An important step in the direction of progress was made with the grouping of the various forms of agricultural activity in the universities and colleges, differentiating them and their forces, and bringing all into a well-knit organization. This provided more definitely for centralized administration and established relationships and responsibilities more clearly. But in the provision for the administrative machinery the process often stopped short of the ideal, probably for reasons of expediency, and in the growth of the institutions it has not caught up with the original plan.

As a result, the general administrative officers in normal times are directing such a variety of important enterprises, constantly becoming more complicated, that only the things of most pressing importance can be gone into thoroughly. This is the case with any large organization; the chief officer can deal only with the larger questions of policy and practice, and must maintain his contact with the various features through associates. But unless provision is made for these in such an institution, many things of real importance to

the welfare of the different enterprises are likely to be passed over with slight consideration or study of all their bearings.

The overworked condition of many of the administrative officers started far back of the war, and is a direct result of the growth which has been taking place. The system of organization had frequently stopped short of the actual needs as they developed with this growth; and when to the usual routine of duties were added calls to exercise active leadership in the agricultural affairs of the State on a war footing, the difficulties of the situation naturally became manifest. There was no shirking, but a ready assumption of the new responsibilities and of an amount of personal work which in some cases can not be maintained indefinitely.

In the history of these colleges the experiment station was usually the first group to be definitely organized and have a responsible head. The station was recognized as representing a definite line of endeavor, with a force of workers and special facilities to meet its needs, methods of its own, and problems and a clientele different from those of the instruction departments.

Hence the provision of an organization and an administrative officer seemed wholly logical, and the office and duties of director became generally recognized. Gradually it was separated from the office of president of the college, wherever it had been combined with that office; and the efficient development of the stations was in large measure the result of the guiding hand of the directors. A good station and a good director usually went hand in hand; and the successful director studied the problems both of his constituents and of his workers.

Events therefore justified the provision of an administrative head to supply leadership to the station, and confirmed the view of the necessity for administration of its funds and its work if the greatest economy and usefulness were to result. Although our station work has changed much in character, and the efficiency of the station staff has increased greatly, the importance of maintaining a station organization, with adequate attention to its affairs and a general supervision of its work and relations, has remained unchanged.

The establishment of the office of dean in the colleges and universities often carried with it the abolition of the directorship of the experiment station as a separate and distinct office. Frequently the mantle of dean fell upon the director of the station, as one who had distinguished himself for administration and perhaps stood nominally at the head of the agricultural work of the college. The situation in the early days was such that the station received a large share of his attention. But in the majority of institutions the duties of this dual officer have greatly changed.

Steady growth of the instruction side of the college, the large development of the experiment station, unprecedented appropriations for wider expansion of the whole institution, and finally the organization of extension work on a novel scale, have increased the working staff many fold and made the duties of administration fully equal to those of the large independent colleges. Indeed, the responsibilities and the internal and external relationships of the dean and director in our larger institutions are now often more exacting than those of president of many of the colleges. It is little wonder then that the dual position of dean and director has made it difficult or impossible to give the attention to the station work which it formerly received, unless special provision is made for assistance.

Nor is this overburdened condition confined to the institutions having this combined officer. Where the position of director is retained, he often has manifold duties outside of that office, and may serve as nominal head of all the agricultural work, or as head of an independent department of the college, or even as director of extension work. His relationships to the agricultural interests and to the people of the State, like those of the dean, often make large demands upon his time. Hence it frequently happens that the director of the station is much more than the responsible head of the research department of the college, and needs to have his office carefully organized to discharge his functions.

The present situation in respect to the office and duties of those in charge of the stations is shown in the following analysis.

In twenty-four institutions the office of dean of agriculture and director of the experiment station is combined in a single person. In other words, the dean or head of all the agricultural work in the institution is likewise director of the experiment station, and there is no separate officer or associate to look especially after the latter's affairs. In six States the dean and director of the station is also director of agricultural extension, an office sufficiently engrossing in most instances to warrant a separate head; and in eight cases the dual officer serves as head of an important subject matter department in the institution. In one instance the combined dean and director acts as State leader of county agents, and in at least three others he has additional duties of an exacting nature.

In twenty-six institutions the director of the station is an independent officer, reporting directly to the head of the institution. In five of these cases he is likewise director of agricultural extension, and in several of the remaining cases he is in charge of a division in the college having both teaching and investigation. In several instances the overworked condition of these dual officers and its effect upon the efficiency of administration have already been recognized,

and steps are under way to relieve the situation. In others the desirability of such relief is indicated.

While the congested administrative situation is a result of the general growth of the agricultural affairs of the college, the inauguration of extension work is often a large factor. This has brought a new set of problems and has added materially to the administrative burden upon the dean and director, even though his office is organized with a competent extension director. It has broadened the external relations through cooperation, and being in an evolutionary stage without precedent to guide action, it has required careful study and many important decisions.

This new activity has had the natural effect of taking away from the experiment station a considerable measure of the thoughtful planning and consideration it previously enjoyed. Indeed, this has been one of the most noticeable effects of the extension work upon the experiment station. Theoretically, the station work has been undergoing something of an adjustment to fit it into its new place, but with so much to divert attention to other channels it has rarely been possible to give it more than secondary consideration. One dean and director, who was also director of extension, recently stated that the extension business had probably occupied nearly or quite three-quarters of his time.

This is the fault of no one, least of all of the heavily burdened officers who are trying to meet the demands of their growing work; but it is a condition which seems not to be adequately realized.

In many ways the station work is most liable to neglect or inadequate supervision if the administrative head of the college is overburdened. The station work, being in the hands of capable experts and of a nature which requires time rather than constant direction, will usually run smoothly for an indefinite period, with little likelihood of friction or difficulties which call for action. The result of any neglect it suffers is largely a cumulative one, likely to be reflected in the general internal condition, in the program of operations, and a laxity in publication, which in turn affect its highest efficiency.

To afford anything more than a quite general supervision of the experiment station and its activities under present conditions will usually require some special provision for it, such as an associate who stands between the dean's office and the various departments of the station. Unless this is done, there is danger that there will not be an intimate contact with the station affairs and that many matters which are vital to the welfare of the station, but in themselves may not be sufficiently insistent to command attention, will be allowed to drift or the situation result in an increasing degree of independence. In only a quite limited number of cases has such special provision

been made. The dean may have an executive clerk who looks out for correspondence, the handling of requisitions and bills, follows up the budget, keeps track of manuscripts for publication, and similar routine matters, but in only two or three instances has a technical associate been provided to maintain a contact with the workers, give the station coherence, follow its needs, and aid in shaping its course as a distinct branch of the institution.

One evidence of deficient administration and inadequate attention is the tendency for the work of a station to become in a certain sense stereotyped. Lines or projects which have been established are allowed to continue from year to year for a long time without critical examination as to their actual progress or the promise they offer of successful outcome. In some cases there may be a failure of the leaders to give the data and the experiments the critical, thoughtful study from year to year that is needed—a failure to measure the actual progress from one season or one stage to another, or to ascertain whether the method of procedure which is followed is proving adequate to the original purpose and the need. This may result in mainly routine procedure, lacking the vital force of research. For, as has been said, "neither logic without observation, nor observation without logic, can move one step in the formation of science."

There are some indications that we are mainly marking time in certain lines of investigation, and especially in some of the projects, because the end of the resources has apparently been reached for the time being. Some things can not be successfully attacked or worked out because the necessary stage of scientific knowledge has not yet been reached. A new inspiration or, in some cases, another set of postulates is needed to rid the work of being superficial and ineffective. There is a failure to acknowledge such limitations or to be guided by the weaknesses of the undertaking. Projects whose plan and method are apparently not competent, and which are not being strengthened by new features or by a division of the problem, are continued from year to year in a hope that the accumulation of data without change may eventually shed some light. This is one of the first evidences of lack of critical supervision, or of lack of time on the part of the leader to examine his results and his method critically.

Such activity is unproductive because it is unprogressive in plan and unconstructive in results. The first essential of research is a theory, an hypothesis on which a plan of attack is devised and a method worked out. If the theory does not prove sound or the method adequate, new ones need to be devised. There is a waste of time and funds unless there is an effort to determine, to the best of the investigator's judgment, whether the theory and the method are

proving adequate and enabling progress. The excuse that data are being accumulated is not sound unless it seems reasonably clear that the added data are marking progress and that the process is not leading around in a circle.

Investigation is a serious business. It requires hard study in outlining the problem as well as in its conduct. The separate experiments comprising it are only means to an end, which are of relatively little account in themselves unless they meet the needs and are assimilated in the general plan. The kind of study demanded requires time for concentration and an intensity which makes a man sweat. It is a searching inquiry.

It not infrequently happens that station workers left to themselves stray outside the economic field, far beyond the bounds of an agricultural experiment station. They fail to keep the natural limitations of their problem in view, or, becoming engrossed with special scientific aspects, are led far beyond the needs of the problem itself, and neglect to return to it until much time and expense have been diverted. It is as though a botantist studying a plant disease and finding a class of uneconomic plants which also served as hosts, should allow himself to be led away into an exhaustive study of the structure and taxonomy, etc., of these hosts, far beyond the particular relationships of these to his problem. No narrow view of science is implied in the maintenance of reasonable boundaries to the function and field of an experiment station. But it is frequently a matter which calls for the discriminating attention of the administrative officer.

Then again the general program of work needs thoughtful and studious consideration to make the station's course one of progress and suited to the special needs. Each station ought to have a fairly definite plan, varied as conditions may require. The revision of this plan, the checking of work which has reached its conclusion or become unproductive, and the introduction of new features can only be done by a general officer and usually requires considerable study.

New projects need consideration from the standpoint of expediency and their relations to the general program, as well as their other merits. They should be practicable in that the end sought seems promising of attainment. The method of procedure should be sound and competent to the purpose, as viewed from the standpoint of the existing stage of science, and it should be evident that advantage has been taken of all available information on the subject. The fact that many of the station investigators are young and with relatively limited experience makes such an examination especially helpful. There is evidence, however, that new projects are not always subjected to such close, discriminating scrutiny.

Again, inadequate supervision may result in long delay in publishing results or in making progress reports. Many workers are prone

to take up new lines of work instead of using the time to digest and publish what they have already acquired. This is the explanation why practical results of importance sometimes remain for a long time unprinted. Unfortunately a considerable amount of our station work is behind in publication, much of it still in the form of the original notes. Hence, when a demand like the present comes, with a need for all available data and results having a practical value, the work of compilation must be speeded up and conclusions made ready for application. To guard against unnecessary delay in publication and see that the product of station work is promptly placed before the public is a matter to which the director may well give systematic attention.

Our agriculture is more and more drifting into a condition where the highest efficiency will be required. This is evident from the increase in population, the higher price of land, the deficiency of soils, the need for vigilance in controlling or evading diseases and insect pests, the increasing problems of economical meat production, and so on throughout the whole range of the agricultural industry. There is every reason, therefore, for maintaining our agricultural investigation upon a high plane of efficiency, a process which requires not alone well trained men but effective administration.

Efficiency is a term so overworked and misused that it has lost some of its force as applied to scientific institutions. Whether or not we like the term as employed by investigating bodies, it is an end which must be striven for intelligently. We are now contending with a nation which exemplifies this trait to a high degree, and which shows how far its course in agriculture as well as in other things has been shaped toward attaining it. Our investigation will need to be as efficient as it can be made after the war, as well as to meet present needs. This suggests a kind of administration which gives direction to the work as a whole and counsel in individual cases, encourages deliberation, and exercises restraint where necessary.

### RECENT WORK IN AGRICULTURAL SCIENCE.

#### AGRICULTURAL CHEMISTRY-AGROTECHNY.

A text-book of organic chemistry, E. V. McCollum (New York: The Macmillan Co., 1916, pp. XIII+426, figs. 25).—In this volume the effort of the author has been to select, for the purposes of illustration of a class of compounds, such compounds as are of biological importance and interest rather than of technical or synthetical.

The synthesis of protein substances, P. E. Verkade (Chem. Weekbl., 14 (1917), No. 3, pp. 89-104).—This is a general discussion of protein substances, including the synthesis and analysis of the material and of intermediate products.

The phytic acid of the wheat kernel and some of its salts, P. W. BOUTWELL (Jour. Amer. Chem. Soc., 39 (1917), No. 3, pp. 491-503).—This paper consists of two parts.

In part I (pp. 491-499), the work on phytic acid is reviewed, and the lack of uniformity in the results of the analysis of the acid and its salts which have been previously published indicated.

Phytin free from inorganic phosphates has been prepared both from wheat bran and wheat embryo by precipitation from a boiling acetic acid solution. The product obtained was a crystalline calcium-magnesium salt, insoluble in water. It did not agree in composition with any simple calcium-magnesium salt of inosit hexaphosphoric acid, and is indicated as representing a new compound from wheat not previously described. The free acid has been separated from this preparation and differs from the sample previously described in that it is a solid substance readily undergoing spontaneous decomposition during drying in vacuum.

Crystalline barium salts have been prepared from the phytin obtained both from the wheat embryo and the wheat bran by the new procedure. "The barium salt crystallized from the cold dilute hydrochloric solution agrees in composition with an equi-molecular mixture of the tri- and tetra-barium salts of inosit hexaphosphoric acid. The barium salts crystallized from the dilute hydrochloric acid solution on boiling do not agree in composition with any salts of inosit hexaphosphoric acid, but with a mixed salt consisting of two molecules of tri-barium inosit hexaphosphate and one molecule of tri-barium inosit tetraphosphate." It is indicated that "phytin exists in the wheat kernel as salts of inosit phosphoric acid, and that phytic acid is an ester of inosit and phosphoric acid."

II. Concerning the phytase of wheat bran and wheat embryo (pp. 499-503).—
"In hydrochloric acid of 0.2 per cent concentration the hydrolysis effected by the enzym in wheat bran as indicated by the production of inorganic phosphoric acid is inhibited, and is only about one-third as great as in the case of 0.1 per cent hydrochloric acid, the concentration of acid in which the enzym exhibits its maximum activity." Dry heat was found to increase the amount

of inorganic phosphorus extracted from the wheat bran, without apparently destroying the enzym. Formaldehyde had no effect on the activity of the phytase. The phytin-splitting enzym was found in the wheat embryo. The maximum activity was evident in the presence of 0.1 per cent hydrochloric acid, but was inhibited by 0.2 per cent hydrochloric acid. The enzym is practically destroyed by 0.4 per cent acid.

See also previous notes by Clarke (E. S. R., 32, p. 16) and Anderson (E. S. R., 31, p. 707; 33, p. 11).

Studies on the forms of d-glucose and their mutarotation, C. S. Hudson and J. K. Dale (Jour. Amer. Chem. Soc., 39 (1917), No. 2, pp. 320-328).

The influence of amino-acetic acid and α-amino propionic acid on the action of alkali on glucose, H. I. WATERMAN (Chem. Weekbl., 14 (1917), No. 4, pp. 119-124).—Analytical data submitted and discussed show that the influence of alanin on the action of alkali on glucose as regards the change in polarimetric readings is similar to that exhibited by glycocoll. For equal weights of the materials the action of alanin, however, is not so marked.

It is indicated that the reactions involved are being further studied and will be published in a future contribution.

Notes on some fatty oils, S. Uchida (Jour. Soc. Chem. Indus., 35 (1916), No. 21, pp. 1089-1093).—These pages give data relative to the yield and physical and chemical constants of the oils of Para rubber tree seed (Hevea brasiliensis), shiromoji seed (Lindera triloba), Calophyllum inophyllum, Hernandia seed (Hernandia peltata), hakuunboku seed (Styrax obassia), akebi seed (Akebia quinata), kuromoji seed (L. serica), aburachan seed (L. pracox), magnolia fruit, magnolia flesh, magnolia seed (Magnolia hypoleuca), and tea seed (Thea chinensis).

The effect of anesthetics and of frosting on the cyanogenetic compounds of Sorghum vulgare, J. J. Willaman (Jour. Biol. Chem., 29 (1917), No. 1, pp. 37-45).—Sorghum leaves exposed to chloroform, ether, and alcohol vapors yielded more hydrocyanic acid, both glucosidic and nonglucosidic, than the normal leaves. The anesthetics thus apparently appeared to stimulate both the hydrolytic and the synthetic action of the glucosidic enzyms. This case is considered as a demonstrated enzym synthesis in vivo.

"Enzym powder prepared from chloroformed leaves was about twenty-five times as active toward amygdalin as the powder from untreated leaves. Frosting also causes an increased yield of both glucosidic and nonglucosidic hydrocyanic acid. This is partly due to a rupturing of the cells, and partly to disturbed enzym equilibrium."

The chemical composition of the placenta, F. Fenger (Jour. Biol. Chem., 29 (1917), No. 1, pp. 19-23).—Analytical data of the fresh tissue and the desicated fat-free material of the two portions of the placenta of a cow are reported in detailed tabular form and discussed. The data show that the constituents of the uterine placenta in general remain comparatively uniform throughout gestation, while the fetal placenta varies considerably at the different stages of pregnancy.

Some observations on the influence of humidity on the physical constants of paper, O. Kress and P. Silverstein (Jour. Indus. and Engin. Chem., 9 (1917), No. 3, pp. 277-282, figs. 3).

Inflammability of carbonaceous dusts, H. H. Brown (Jour. Indus. and Engin. Chem., 9 (1917), No. 3, pp. 269-275, figs. 7).

The chemistry of wood decay.—I, Introductory, R. E. Rose and M. W. Lisse (Jour. Indus. and Engin. Chem., 9 (1917), No. 3, pp. 284-287).—Detailed analytical data of samples of sound, partially decayed, and totally decayed heartwood of Douglas fir are submitted and briefly discussed.

The data show that the progress of decay may be readily followed by chemical methods, and that even a comparative cellulose determination might serve to detect incipient decay, since in the cases studied decay was accompanied by a very rapid fall in cellulose content. The lignin was found to be far more resistant to decay than cellulose.

The value of a study of the process and products of decay in relation to studies on the composition of the organic substances in soil is indicated.

Tyrosinase, a mixture of two enzyms, T. Folpmers (Chem. Weekbl., 13 (1916), No. 48, pp. 1282-1289).—The author reviews the literature on the products of tyrosinase action, and submits some experimental data which substantiate the contention that the reaction consists of a deaminization (by oxidation) and then a further oxidation.

An efficient desiccator, L. S. Pratt (Jour. Amer. Chem. Soc., 39 (1917), No. 2, pp. 271-273, fig. 1).—The construction and use of the apparatus is described in detail. The advantages claimed for this type of desiccator are simplicity of construction and operation, rapidity of desiccation, adaptability to vacuum desiccation, and adaptability to desiccation at elevated temperatures.

A simple gas generator, R. O. Fernandez (Jour. Amer. Chem. Soc., 39 (1917), No. 2, p. 271, fig. 1).—A simple apparatus which is indicated as yielding satisfactory results is described by a diagram.

A new direct reading refractometer with uniformly divided scale, G. W. Moffitt (Jour. Indus. and Engin. Chem., 9 (1917), No. 3, pp. 305-309, figs. 4).—The theory, construction, and manipulation of a new form of apparatus are described in detail.

Further studies on a numerical expression for color as given by the Ives tint photometer, O. Kress and G. C. McNaughton (*Jour. Indus. and Engin. Chem.*, 9 (1917), No. 3, pp. 282-284, fig. 1).—See also a previous note (E. S. R., 36, p. 207).

Determination of carbon dioxid in carbonates by diminished pressure, J. B. ZINN (Jour. Amer. Chem. Soc., 39 (1917), No. 2, p. 270).—The author recommends the use of an 8-liter aspirating bottle instead of the usual suction pump as being more satisfactory and yielding excellent results in this determination.

The Penfield test for carbon, W. G. MIXTER and F. L. HAIGH (Jour. Amer. Chem. Soc., 39 (1917), No. 3, pp. 374, 375, figs. 3).—The application of the well-known reaction for determining carbon and carbonates, which consists of heating a mixture of the sample with lead chromate in a small horizontal tube, near the open end of which is placed a drop of barium hydroxid solution, is described. In a determination of the delicacy of the test, using a mixture of silicon carbid and aluminum oxid, 0.01 mg. silicon carbid (containing 0.003 mg. carbon) was found to give an unquestionable reaction. It is indicated that the reaction could undoubtedly be made more delicate by using a minute drop of barium hydroxid solution and observing the result with a microscope.

The volumetric determination of tin, R. L. HALLETT (Jour. Soc. Chem. Indus., 35 (1916), No. 21, pp. 1087-1089).—This is a general review and discussion of the procedures for the determination of tin. A bibliography of 40 references to the literature cited is appended.

On the determination of potassium as perchlorate, G. P. BAXTEB and M. KOBAYASHI (Jour. Amer. Chem. Soc., 39 (1917), No. 2, pp. 249-252).—From solubility and analytical data reported the authors submit, as recommendations for the determination of potassium as perchlorate in the presence of sodium, the use of absolute alcohol for washing, the use of a low temperature in washing (0° C.), and the use of a platinum-sponge crucible. The value of the use of a washing liquid saturated with potassium perchlorate, as previously

suggested, is indorsed, as well as the solution and recrystallization of the precipitate in the presence of rather large amounts of sodium salts.

The use of methylene blue in chemical analysis and its special application for the determination of perchlorates in Chile saltpeter, A. Monnier (Ann. Chim. Analyt., 22 (1917), No. 1, pp. 1-6).—The author has found that in dilute solutions iodids, perchlorates, persulphates, bichromates, permanganates, ferricyanids, metavanadates, molybdates, and tungstates give a precipitate with a solution of methylene blue. For the distinction of ferricyanids from ferrocyanids, iodids in iodates and periodates, persulphates in the presence of other sulphur acids, and perchlorates in chlorates or other acids of chlorin the reactions are characteristic. A colorimetric procedure for the determination of perchlorate in saltpeter which depends on the production of a violet precipitate with a bronze fluorescence is described in detail. The effect of the presence of iodids in the Chile saltpeter, which can easily be removed as silver iodid, is noted. The other salts present in crude saltpeter are without effect on the production of the color.

Studies on the phenoldisulphonic acid method for determining nitrates in soils, C. W. Davis (Jour. Indus. and Engin. Chem., 9 (1917), No. 3, pp. 290–295).—The author studied the various factors which had previously been found to influence the accuracy of the results obtained by the phenoldisulphonic acid procedure and found that ammonia fumes did not affect the results of the determination. Light was found to affect the color material, so that the readings to influence the accuracy of the results obtained by the phenoldisulphonic acid acid had no effect on the results, nor did the temperature of the solution at the time the alkali is added to develop color show any variation in results except at freezing temperature, when a loss of 4 per cent resulted. Potassium chlorid added just before and just after the developing of the color by potassium hydroxid produced no loss of nitrates. With the use of uniform amounts of phenoldisulphonic acid (2 cc.) the maximum loss of nitrates was 30 per cent. When proportional amounts of the reagent were used (2 cc. for each 0.025 mg.) the maximum loss was reduced to 10 per cent.

A modified procedure in which the loss of nitrates is prevented by keeping the solution alkaline during evaporation is described. The addition of two drops of hydrochloric acid in a solution containing 25 parts per million of nitrates caused a loss of all nitrates. By keeping the solution alkaline during evaporation there was no loss even in the presence of chlorids, sulphates, and carbonates. Potassium alum may be used as a flocculent in preparing the soil solution without a loss of nitrates.

The work of Lipman and Sharp (E. S. R., 28, p. 610) was checked up and similar results obtained.

A bibliography of 35 references to the literature cited is included.

A note on the detection and estimation of small amounts of methyl alcohol, E. Elvove (Jour. Indus. and Engin. Chem., 9 (1917), No. 3, pp. 295-297).—In a study of the application of Deniges test for methyl alcohol to its colorimetric estimation the author found that by reducing the proportion of ethyl alcohol from 10 per cent, as recommended by Simmonds, to 0.5 per cent the accuracy of the method was markedly increased.

For preparing the reagent the following procedure was found to yield the best results: Two-tenths gm. finely powdered fuchsin is dissolved in 120 cc. hot water and cooled to room temperature. Two gm. of anhydrous sodium sulphite dissolved in 20 cc. of water is added to the fuchsin solution, after which 2 cc. hydrochloric acid (specific gravity 1.19) is added and the whole diluted to

<sup>&</sup>lt;sup>1</sup> Compt. Rend. Acad. Sci. [Paris], 150 (1910), No. 13, pp. 832-834.

<sup>&</sup>lt;sup>3</sup> Analyst, 37 (1912), No. 430, pp. 16-18.

200 cc, with water. After standing for about an hour this solution is ready for use. A solution kept in a closed container for six weeks was found to be as reliable at the end of that time as a freshly prepared solution.

When formaldehyde is present in the solution to be tested it should be accurately determined and the same amount used in the standards.

Cellulose, C. F. Cross, E. J. Bevan, and C. Beadle (London and New York: Longmans, Green & Co., 1916, new ed., XVII+328, pls. 14).—This edition is in the main a reprint of the former edition with a small portion of the text rewritten and the addition of an appendix which includes an account of the more important recent contributions. The subject as a whole treats of the chemistry of the structural elements of plants with reference to their natural history and industrial uses, and is divided into three parts, the typical cellulose and the cellulose group, compound celluloses, and experimental and applied chemistry.

A quantitative method for the determination of arginin in proteins, B. C. P. Jansen (Chem. Weekbl., 14 (1917), No. 4, pp. 125-129).—A new method is proposed which consists of hydrolyzing a suitable sample of protein with hydrochloric acid (specific gravity 1.19), removing as much of the excess hydrochloric acid as possible by evaporation, and neutralizing the hydrolyzate with alkali until slightly alkaline to litmus or neutral to neutral red. Aliquot portions are then treated simultaneously with solutions of arginase and urease for about 24 hours, after which time the ammonia from the ammonium carbonate formed is liberated by a saturated solution of potassium carbonate and distilled by aeration into standard acid. A blank determination is made with an aliquot and urease alone to determine the presence and amount of urea in the hydrolyzate. One molecule of arginin yields one molecule of ornithin and urea, so that the amount of arginin originally present is readily calculated from the amount of ammonia obtained.

The method is considered to yield more accurate results than the procedure of boiling the hydrolyzate with alkali as described by Van Slyke (E. S. R., 26, p. 22).

The preparation of the arginase from the fresh liver of a dog or cat is described in detail.

Red peppers, F. M. Boyles (Jour. Indus. and Engin. Chem., 9 (1917), No. 3, pp. 301, 302).—Analytical data of a number of samples of South Carolina capsicum, Bombay capsicum, Japan capsicum, Mombasa chilies, and miscellaneous capsicums and chilies are reported in tabular form. The data include total ash, insoluble ash, fiber, total ether extract, and volatile and nonvolatile ether extract.

It is indicated that the present standards for red peppers (E. S. R., 18, p. 459) are in need of revision and the following is submitted: Total ash 7.5 per cent, hydrochloric acid-insoluble ash 1 per cent, nonvolatile ether extract 14 per cent, and crude fiber 29 per cent.

Vinegar: Its manufacture and examination, C. A. MITCHELL (London: Charles Griffin & Co., Ltd., 1916, pp. XVI+201, pls. 5, figs. 49).—This volume discusses the subject in detail under the general topics of historical introduction, theories of acetic fermentation, acetic bacteria, chemical reactions in acetification, acetic acid, preparation and acetification of the gyle, treatment of the crude vinegar, methods of examination, and characteristics of different vinegars. Appendixes contain British import duties on vinegar and acetic acid and French duties on vinegar.

The volatile reducing substance in cider vinegar, R. W. Balcom (Jour. Amer. Chem. Soc., 39 (1917), No. 2, pp. 309-315).—The author has shown that the volatile reducing substances in cider vinegar consist largely, if not wholly,

of acetylmethyl-carbinol and that this substance is a normal constituent of the vinegar.

The experimental procedures used in the investigation are described in detail. The analysis of Peruvian bark, J. W. Commelin (Meded. Kina Proefstat. [Dutch East Indies], No. 1 (1912), pp. 38).—This pamphlet describes and discusses in detail procedures for the determination of moisture, total alkaloids, quinin, and cinchonidin. Simplicity of methods was the aim, since they were to be used in cultural experiments. Formulas for calculating the quantity of total alkaloids and cinchonidin are included, together with correction tables for polarimetric readings, etc.

The determination of the various forms of nitrogen in forage plants, N. Passerini (Ann. Chim. Appl. [Rome], 6 (1916), No. 5-8, pp. 162-164).—The author describes a procedure by which the forms of nitrogen in the hydrolyzed sample\_are determined as nuclein nitrogen, amino acid nitrogen, ammonia nitrogen, and preformed amid nitrogen. The procedure consists essentially of determining the pure protein according to the procedure of Kellner in a 1 gm. sample. In another 5 gm. hydrolyzed sample, after treating according to Kellner's method, the copper is removed with hydrogen sulphid and the ammonia determined in an aliquot of the filtrate. The nonhydrolyzable nitrogen, considered to be nuclein, is then determined in the residue. The amino acid nitrogen is determined by subtracting the sum of the ammonia and nonhydrolyzable nitrogen from the total protein nitrogen.

A table showing the distribution of nitrogen in whole wheat, wheat bran, wheat flour, maize, beans, and vetch is submitted.

The estimation of hydrocyanic acid and the probable form in which it occurs in Sorghum vulgare, J. J. Willaman (Jour. Biol. Chem., 29 (1917), No. 1, pp. 25-36).—The author, at the Minnesota Experiment Station, considers the methods in general use for the determination of hydrocyanic acid in plant tissues of questionable accuracy because of the difficulty of obtaining complete hydrolysis of the glucosids by means of acids and because of the retention of the cyanid from distillation by the tissues involved.

Analytical data show that the hydrolysis of durrin, the glucosid in sorghum, is best accomplished by autolysis, the reaction taking place rapidly at 45° C. "Retention of hydrocyanic acid by the tissues during distillation can not be prevented by the presence of tartaric acid, nor can it appreciably be lessened by distilling under reduced pressure." Hydrocyanic acid occurs in S. vulgare in two forms, as a glucosid and as a nonglucosid, the nature of which is yet unknown. The nonglucosidic form is considered to be probably responsible for the poisoning of stock. This form can be distinguished from the glucosidic by grinding the leaves in the presence of 5 per cent tartaric acid to prevent any enzym action and then distilling.

Relation of the fat in milk to the solids-not-fat, L. P. Brown and C. V. Ekroth (Jour. Indus. and Engin. Chem., 9 (1917), No. 3, pp. 297-299, fig. 1).—
The authors have devised a zone chart from the figures for percentage fat and percentage solids-not-fat of a large number of published analyses of milk. The chart shows the approximate chemical composition of normal milk and is intended as a guide in fixing legal standards and also in detecting adulteration.

It is indicated that "a milk standard having regard only for the total solids is illogical. Most of the legal milk standards in force in the several States of the Union as well as that of the Federal Government are unbalanced and, therefore, incapable of enforcement."

The detection of preservatives and coloring matter in milk, I. M. Kolthoff (Pharm. Weekbl., 53 (1916), No. 48, pp. 1609-1618).—The author briefly

reviews the preservatives and coloring matters commonly used and the procedures for their detection by the official Dutch methods.

A considerably shorter scheme for routine examination is proposed, in which formalin is detected by phenol sulphonic acid, hydrogen peroxid by vanadic acid in sulphuric acid, and carbonate by the difference in acidity before and after heating. The coloring matters are determined by the usual tests. An outline for the detection of salicylic, benzoic, and boric acids and fluorids in the ether extract of milk is also submitted.

A new method for the analysis of rancid fats and oils, G. Issoglio (Ann. Chim. Appl. [Rome], 6 (1916), No. 1-2, pp. 1-18).—Rancidity and its detection in oils and fats is briefly reviewed, and a new procedure by which a new constant called the oxidation number is determined is described. This constant is represented by the milligrams of oxygen necessary to oxidize the volatile organic material obtained by steam distillation from 100 gm. of the sample. The material is oxidized with standard permanganate and the excess permanganate titrated against oxalic acid.

Analytical data showing the oxidation number, acid index, and iodin number of a number of pure and rancid olive oils, three samples of peanut oil, two each of sesame and soy-bean oil, rape-seed oil, cottonseed oil, butter, vegetable butters, oleomargarin, and some animal fats are submitted. For pure edible oils the constant was found generally to range from 3 to 10. For rancid fats it was much higher, a value of 15 being an indication of slight rancidity or some change in the material. The new constant proposed is considered to be of value in evaluating oils, and should be determined with the other constants in the usual examination of oils.

[Report of the analysis of various samples] (Dept. Landb., Nijv. en Handel [Netherlands], Verslag. en Meded. Dir. Landb., No. 5 (1916), pp. 52-59).—These pages contain brief notes on the analysis of various samples of soil, plant products, water, dairy products, insecticides, fungicides, and fertilizers.

Fruit drying, W. J. Allen (Agr. Gaz. N. S. Wales, 28 (1917), No. 1, pp. 13-29, figs. 7).—These pages describe procedures for the curing and drying of apricots, peaches, nectarines, prunes, apples, pears, figs, raisins, sultanas, and currants as practiced in New South Wales.

Sulphitation in white sugar manufacture, F. Maxwell (London: Norman Rodger, 1916, pp. XII+72, pls. 3, figs. 8).—This is a general discussion of the subject under the following topics: Sulphur, its origin, preparation, and properties; sulphurous acid, its preparation, chemical properties, and action; generating plants for sulphurous acid gas and sulphitation vessels for juice and sirup; the control of the sulphurous acid gas generating station; analysis of the sulphurous acid gas; action of sulphurous acid on juices; principles of the application of sulphitation to juice; sulphitation of the sirup and of molasses; the sulphitation process in practice; processes adopted by the leading white sugar countries; and a general summary.

A study of commercial beech wood crossote, H. K. SMITH and S. F. ACREE (Jour. Indus. and Engin. Chem., 9 (1917), No. 3, pp. 275, 276).

A method of producing crude wood creosote from hardwood tar, R. C. Judd and S. F. Acree (Jour. Indus. and Engin. Chem., 9 (1917), No. 3, pp. 276, 277).

#### METEOROLOGY.

Relation of weather to the amount of cotton ginned during certain periods, J. B. Kincer (U. S. Mo. Weather Rev., 45 (1917), No. 1, pp. 6-10, figs. 2).—Data regarding cotton ginned, as related to temperature and fair days during the 11-year period 1905-1915, are presented in tables and diagrams.

The conclusion is reached that "a forecast of the size of the cotton crop, based on the ginning reports, has a much greater value when consideration is given to the influencing weather factors... than when the reports alone are considered. For example, if temperatures during the critical months of growth be high and thus conduce to a rapid advancement and early maturity of the crop, and in addition the weather be favorable for picking during the period covered by a given early ginning report, say September 1 to September 25, it may be safely considered that the percentage of the total crop ginned during the period will be much in excess of the average and the final yield less than that apparently indicated by the actual amount ginned to that date....

"If, however, these modifying weather influences work in opposition and thus largely neutralize each other then the amount ginned, whether above or below the average, gives a better direct indication as to whether the final yield will also show values above or below the average than in the other case. Furthermore if the temperature conditions were unfavorable for early maturity and the percentage of fair days during the ginning period small, it may be safely assumed that the final yield will be larger than apparently indicated by the actual amount ginned.

"In studying early ginning reports in connection with the two modifying weather factors under discussion, it must be borne in mind that temperature has the dominating influence and should be given greater weight, but later, say for the period from September 25 to October 18, the amount of fair weather during the period itself takes precedence. . . .

"The fact that favorable temperatures during the early growing season are also conducive to comparatively large yields, as well as to early maturity of the crop, should likewise be considered, and it might also be noted that early maturity, in effect, postpones the date of first killing frost in fall by an equal number of days represented by the earliness of the crop and thus reduces the chance of damage from this source."

Monthly Weather Review (U. S. Mo. Weather Rev., 45 (1917), Nos. 1, pp. 1-46, pls. 10, figs. 2; 2, pp. 47-90, pls. 10, figs. 3).—In addition to weather forecasts, river and flood observations, and seismological reports for January and February, 1917; lists of additions to the Weather Bureau Library and of recent papers on meteorology and seismology; notes on the weather of the months; solar and sky radiation measurements at Washington, D. C., during January and February, 1917; condensed climatological summaries; and the usual climatological tables and charts, these numbers contain the following articles:

No. 1.—Notes on the Horizontal Rainbow, by S. Nakamura; Demonstration of Horizontal and Intersecting Rainbows, by K. Otobe; Aurora of August 26, 1916, Observed at Hessel, Mich., by F. E. Nipher; Relation of Weather to the Amount of Cotton Ginned during Certain Periods (illus.), by J. B. Kincer (see p. 114); Grasshoppers at Sea, by W. E. Hurd; National Meteorological Service of Colombia; Another "Dark Day of May 19, 1780"? Classification of the Hydrometeors, II, by G. Hellmann; Notes and Comments on Hellmann's Classification of Hydrometeors; Alternate Deposition of Rauhreif and Rauheis (illus.), by W. R. Blair; and Ammonia in Dew (see p. 116).

No. 2.—The Smoke Cloud and the High Haze of 1916, by H. H. Kimball; Free-air Data in the Hawaiian Islands, July, 1915, by W. E. Ellis; Weather Bureau Exhibit at the First Pan American Aeronautic Exposition (illus.), by W. R. Gregg; Sound Areas of the Explosion at East London, January 19, 1917, by C. Davison; Parhelic Circle with Two Pairs of Parhelia at Fargo, N. Dak.; Competency of Wind in Land Depletion, by C. R. Keyes; Reduction

of Air Temperatures at Swedish Stations to a True Mean, by N. Ekholm; Formation of Winter Stratus, Depth of Northeast Wind, by D. Manning; Atmospheric Circulation and the Weather in Argentina, by H. H. Clayton; The Argentine Meteorological Service; and Report of the Meteorological Station at Berkeley, Cal., for the Year Ending June 30, 1915 (illus.), by W. G. Reed.

Climatological data for the United States by sections (U. S. Dept. Agr., Weather Bur. Climat. Data, 4 (1917), Nos. 1, pp. 238, pls. 2, figs. 4; pp. 246, pls. 2, figs. 7).—These volumes contain brief summaries and detailed tabular statements of climatological data for each State for January and February, 1917, respectively.

Meteorological records (Hawaii Sta. Rpt. 1916, p. 43).—Monthly summaries of observations from January 1 to June 30, 1916, on temperature, precipitation, and rainy and clear days at the Glenwood substation, Hawaii, are tabulated.

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. Ostrander and W. P. Saunders (Massachusetts Sta. Met. Buls. 339-340 (1917), pp. 4 each).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during March and April, 1917, are presented. The data are briefly discussed in general notes on the weather of each month.

Free-air data at Drexel aerological station: January, February, and March, 1916 (U. S. Mo. Weather Rev., Sup. 5 (1917), pp. 59, pls. 3).—The results of 138 free-air observations at Drexel, Nebr., by means of kites are reported in detail. "The means of the highest points reached with the kites are 2,722 meters above sea level in January, 2,869 in February, 2,631 in March, and 2,731 for the period."

Ammonia in dew (Met. Off. [Gt. Brit.] Circ. 7 (1916), p. 4; U. S. Mo. Weather Rev., 45 (1917), No. 1, p. 19).—Samples of dew collected on glass plates 12 in. square exposed 1 ft. above the ground over grass land in fine weather from September 23 to December 6, 1914, and within one hour of sunrise, showed no nitrates, traces of chlorids, and a comparatively large proportion of ammonia, namely, 7.5 and 5 parts by weight in 1,000,000, respectively.

#### SOILS—FERTILIZERS.

The water content of the soil and the composition and concentration of the soil solution as indicated by the freezing-point lowerings of the roots and tops of plans, M. M. McCool and C. E. Millar (Soil Sci., 3 (1917), No. 2, pp. 113-138).—This paper, prepared at the Michigan Experiment Station, presents the principal results of greenhouse and field studies on the concentration and composition of the soil solution, the water content of soils, and the rate of water movement in soils as measured by the freezing point lowerings of the roots and leaves of plants. Several different soils and plants were used.

It was found that "consistent determinations of the freezing-point depression of plant tissue may be obtained by inserting the thermometer directly into material triturated in the freezing tube. Results with material repeatedly reduced to the point of solidification, repeatedly frozen at low temperatures, and material frozen at low temperatures and macerated or triturated were essentially the same as those obtained by direct freezing of the triturated material.

"The freezing-point depression of sap expressed under great pressure from the aerial portion of the plants studied, previously frozen at low temperatures, was practically the same as that of the material frozen directly, but greater if the pressure is not so great. The freezing-point depressions of the juice expressed from roots frozen at low temperatures were not consistent. It was found necessary to take samples of vegetable material for freezing-point work at the same time of day or else protect the plants from light and retard transpiration, since the freezing-point depression of the leaves was found to increase from morning till noon and decrease again in the evening. It appeared that this change was due to the products of photosynthesis, as well as to the moisture content of the material which decreased from morning till noon and increased again in the evening.

"The concentration of the solution in which roots of Canada field pea and wheat are grown is indicated by the freezing-point lowerings of the root tissues, but on the other hand only rather wide variations are indicated by the freezing-point lowerings of the tops. Changes in the concentration of the soil solution induced by the addition of salts may be detected by determining the freezing-point lowerings of the roots of the plants growing therein. It was found that the tops of the plants are far less sensitive to changes in the concentration of the soil solution.

"The moisture content of soils is closely correlated with the freezing-point lowerings of the roots of the plants in contact with them, due in part at least to changes in the concentration of the soil solution so induced, but again the tops of the plants studied, under both greenhouse and field conditions, prove to be far less sensitive to soil moisture changes, at least until the critical water content is approached. The indications are that the soil solution and the root sap of plants approach each other in concentration at or near the critical (low) water content of the soil. The freezing-point lowering of a given crop growing in widely different soils of high water content were found to differ but slightly. On the other hand, different crops growing on the same soil, under similar conditions, vary appreciably in this respect. The field studies show that crops may be subjected to sudden and very wide variations in the concentration of the soil solution during the growing season."

Twenty-eight references to literature bearing on the subject are appended.

Relation of the water-retaining capacity of a soil to its hygroscopic coefficient, F. J. Alway and G. R. McDole (U. S. Dept. Agr., Jour Agr. Research, 9 (1917), No. 2, pp. 27-71, figs. 4).—Laboratory experiments conducted at the Nebraska Experiment Station with uniform columns of soil of known hygroscopic coefficient and moisture content are reported. The 13 soils used ranged in texture from a coarse sand to a silt loam, with hygroscopic coefficients of 0.6 and 13.3, respectively.

"Five of the loams, placed in capillary connection with the natural subsoil mass, saturated with water, and allowed to stand protected from surface evaporation for several months, lost water until the amount retained bore a close relation to the hygroscopic coefficient, being from 2.1 to 3.1 times this value, according to the particular soil. When a layer of coarse sand or gravel separated the column of loam from the natural subsoil mass or interrupted it, the downward movement of the water in the soil above this layer was much delayed. Where the column consisted of successive 2-in, layers of loams differing widely in texture, the order of their arrangement exerted no influence upon their final water content.

"Soil columns 30 to 36 in. long, while protected from all loss of moisture at the sides and bottom, were freely exposed to evaporation at the surface for periods varying from a few weeks to half a year. The moisture content, originally uniform and lying between 2 and 3 times the hygroscopic coefficient, fell until it reached, at depths below the first foot, an almost constant minimum with the ratio 1.9:2.2.

"Employing 2-ft. columns of 12 different loams, each with an initial moisture content approximately equal to its hygroscopic coefficient, enough water was added to raise the average moisture content of the column to 1.5 times the hygroscopic coefficient, the water being applied in one experiment to the top and in another to the base of the column. After the cylinders had stood for three or four months fully protected from evaporation the distribution of moisture, with regard to the surface to which it had been applied, was found to be the same in both experiments. The maximum distance through which an effect was shown was about 2 ft., but in most cases much less. The maximum final ratio of moisture content to hygroscopic coefficient was found in the section adjacent to the surface of application, where it lay between 1.7 and 2.4. The ratio, while falling within these limits, is not a constant, it not being the same for all the soils that have the same hygroscopic coefficient.

"The water-retaining capacity of the loams, as determined by laboratory experiments, was found to bear a somewhat closer relation to the moisture equivalent than to the hygroscopic coefficient, the ratio varying between 0.8 and 1.2.

"Coarse sands exhibited a behavior very different from that of the loams. The ratio in the surface 6-in. section, even three months after 1 in. of water had been applied to the surface, was as high as 6 or 7, while in the second foot it was only 1. The field studies on coarse sands showed as high a final ratio as was observed in the laboratory experiments. The very limited studies on fine sands indicate that these occupy a position intermediate between the loams and the coarse sands, the ratio of the water-retaining capacity to the hygroscopic coefficient rising as the latter value falls.

"Field studies show that when loams, after rains sufficiently heavy to moisten them thoroughly, are protected from losses by evaporation and transpiration, they lose water by downward movement until the ratio of moisture content to hygroscopic coefficient lies between 1.8 and about 2.5, and accordingly on the uplands of dry-land regions this is the ratio to be expected in the deeper subsoil—the portion below the range of plant roots.

"A comparatively abrupt transition from the moistened soil to the thoroughly exhausted underlying layers, with ratios of 2:2.5 and 1:1.1. respectively, is found even several months after liberal rains have fallen, if the subsoil to a considerable depth had previously been exhausted of available water. The moisture of the deeper subsoil will be able to move upward only so slowly and through such a short distance in a single season that it will be at most of no practical benefit to annual crops. To make use of any portion of the precipitation which penetrates beyond the reach of the roots of annual crops it will be necessary to follow such crops at intervals by deep-rooting perennials."

Twenty-five references to literature bearing on the subject are appended.

Investigations on the acidity of acid mineral soils, I. S. Osugi and T. Uetsuki (Ber. Öhara Inst. Landw. Forsch., 1 (1916), No. 1, pp. 27-52, fig. 1).— On the assumption that the acidity of acid soils is intimately related to their alumina content, the authors conducted experiments in which it was found that when the bases of soils disappear as a result of active weathering and decomposition certain colloidal substances are formed in the soils which actively absorb bases. When such soils are then treated with salt solutions acids are set free. It was found that the alumina in soils is easily dissolved out by hydrochloric acid but not by acetic acid. Therefore, coniderable alumina was found in the filtrate of a potassium chlorid solution of the soil. It is thought that other factors also influence the difference in the intensity of the acidity

of the two filtrates, and that the action of the acids set free by adsorption of bases is important in this connection.

It is concluded best, therefore, to consider an acid soil as one not saturated with bases.

The sulphur content of some typical Kansas soils, and the loss of sulphur due to cultivation, C. O. Swanson and R. W. Miller (Soil Sci., 3 (1917), No. 2, pp. 139-148).—Studies of the sulphur content of eleven samples of typical Kansas soils made at the Kansas Experiment Station are reported. The soils are loams, silt loams, and silty clay loams. Five were from fields in the native sod and six from fields in cultivation for from 30 to 40 years.

The results "show that the percentage loss of sulphur from cultivated soils is proportionately equal to that of organic matter. It has also been shown that the loss of sulphur due to the amount taken up by the crop is insignificant as compared with the total amount which has disappeared from the soil. This means that the sulfofication has been in excess of the needs of the crop and the sulphates produced have leached out of the ground. As measured by crop requirements, sulfofication has been much more rapid than nitrification."

It is further concluded that the loss of sulphur from soil may be a very important factor in the loss of productivity. "Whether or not sulphur is at present a limiting element in the production of crops on Kansas soils, it is apparent that the supply of this essential element is closely related to the supply of organic matter. . . . It would seem that sulphur would become a limiting factor sooner than phosphorus unless sulphur is made available more rapidly than phosphorus. This, however, would not affect the ultimate supply."

Sixteen references to literature bearing on the subject are appended.

Studies in sulfofication, P. E. Brown and H. W. Johnson (*Iowa Sta. Research Bul. 34* (1916), pp. 3-24).—Continuing previous work (E. S. R., 34, p. 19), experiments on the relative effects of gypsum, acid phosphate, rock phosphate alone and with gypsum, and monocalcium phosphate, on sulfofication and on ammonification and the yields of oats in pots are reported. The soil used was a black loam, high in organic matter and of basic reaction.

It was found that "the sulphate content of the soil varied only slightly from one sampling to the next. There were no sudden or striking changes in the amount of sulphates present in soil kept fallow in the greenhouse. The sulphate content of soils in the field is subject to the same influences as the nitrate content, but the effects are probably much less pronounced.

"Calcium sulphate, monocalcium phosphate, acid phosphate, rock phosphate, and rock phosphate plus gypsum increased the sulfofying power of the soil. The sulphate alone and phosphates alone had greater effects than combinations of the two materials as in acid phosphate. All the materials used increased the ammonifying power of the soil, but the differences between the effects of the various substances were not pronounced. The rock phosphate had less effect, however, than the other materials. The sulfofication tests and ammonification tests did not always run parallel, although very similar effects of the materials used, on the two processes, were noted. The phosphorus fertilizers, except monocalcium phosphate, increased the yield of oats on the soil, the acid phosphate to a greater extent than the rock phosphate. The sulphate had no effect on the crop yield. . . .

"The crop yields, sulfofication, and ammonification results were not always parallel. In general, it appeared that on this soil increases in sulfofication were not necessarily parallel with increases in yields. The ammonification results were not conclusive but indicate that materials supplying plant food constituents which are lacking in the soil may be of double value because of

increases in the production of other plant food constituents in an available form."

Further studies on sulfofication in five soils of varying texture and composition showed that "in the use of the free-sulphur-fresh-soil method for testing the sulfofying power of soils, the incubation period should be 14 days at room temperature to give the most conclusive results. Ten days' incubation gave the relative sulfofying powers of soils quite accurately, but the differences were much more distinctive for the longer period.

"Calcium sulphate in ordinary applications had no detrimental effect on sulfofication, but very large applications might decrease the rate of oxidation of sulphur. Calcium carbonate in ordinary applications on acid soils increased sulfofication considerably and even in excessive amounts affected sulphur oxidation favorably. Magnesium carbonate in small amounts increased sulfofication, but in large amounts depressed it even below that in the same soil with its acidity unneutralized. Magnesium carbonate and calcium carbonate in combination exerted a beneficial influence on sulfofication when used in small amounts. Larger applications, however, depressed the oxidation of sulphur. The effects of the combined materials were less than that of the calcium carbonate alone."

Nitrous nitrogen in irrigated soils, J. E. Greaves, R. Stewart, and C. T. Hirst (Soil Sci., 3 (1917), No. 2, pp. 149-154, pl. 1).—This paper, prepared at the Utah Experiment Station, reports a study of the nitrous nitrogen content of soils made in connection with studies of the influence of irrigation water on the movement and production of nitrates in irrigated soils (E. S. R., 27, p. 418).

"The data reported represent some 800 determinations of the nitrous nitrogen of a calcareous soil without crop, cropped to alfalfa, to oats and alfalfa, to oats, to potatoes, and to sugar beets. The water applied to the soil varied from none to 37.5 in. per acre yearly.

"The nitrous nitrogen content of the soil was very low and was about evenly distributed throughout the 10 ft. The total quantity found in an acre of soil to a depth of 10 ft. varied from a trace... up to 17 lbs. per acre.

"No relationship was found to exist between the nitrous nitrogen and the nitric nitrogen content of the soil. The application of irrigation water had no appreciable influence upon the nitrous nitrogen content of the soil, [but] there was a slight seasonal variation. . . . In the alfalfa and the oat soils it was highest in the spring and decreased toward fall, while in the potato and the corn soils it was lowest in spring and increased toward fall. In the fallow the nitrous nitrogen was highest in midsummer. The greatest quantity of nitrous nitrogen was found in the alfalfa soil during the spring, while the least was found under the oats during midsummer. The application of manure to the soil had no appreciable influence upon the nitrous nitrogen content of the soil."

Influence of humus forming materials of different nitrogen-carbon ratios on bacterial activities, P. E. Brown and F. E. Allison (Ioica Sta. Research Bul. 36 (1916), pp. 3-30).—Pot experiments on the influence of materials of narrow and wide nitrogen-carbon ratio on the bacterial activities in Miami sandy loam soil, low in organic matter, are reported.

It was found that "applications of the common humus-forming materials in maximum amounts for farm conditions and in a dried condition increased ammonification, nitrification, and azofication to a considerable extent. Horse manure, cow manure, and rotted manure gave the greatest effect on ammonification in most cases, although timothy hay surpassed the horse manure and cow manure in the extent of its effect in several instances. The oats, straw,

and corn stover gave a smaller effect than the manures, and the legume hays, clover, and cowpeas showed the least effect on ammonification of any of the materials used. Increases in ammonification due to the applications of humusforming materials were independent of the nitrogen-carbon ratio of the materials added and were probably dependent on the chemical composition of the substances.

"The dried-blood fresh-soil method gave better results for ammonification than the casein fresh-soil method. The latter gave better duplicate results, but the differences between different soils were not nearly so pronounced. Some further modification of the casein method seems necessary for its general use.

"Nitrification was increased in much the same way as ammonification, by the various organic materials. The leguminous green manures exerted, however, somewhat greater effects than the manures, and also more influence than the nonlegumes. These results were the opposite of those secured with ammonification, but the differences were not great enough to permit of definite conclusions. Increases in nitrification brought about by the various materials were apparently independent of the nitrogen-carbon ratio in the substances. Indications of a greater effect of materials of a narrower ratio over those of a wide ratio can not be considered conclusive.

"Nonsymbiotic nitrogen fixation was favored by manure to a large extent. Straw, stover, and nonleguminous hays had almost as great an effect as the manures, and the leguminous hays had the least effect of any of the materials used. The nitrogen-carbon ratio of the materials employed were of little or no significance in indicating their effects on azofication. There were indications, however, that nonlegumes and straws might increase azofication in soils to a large enough extent to make their use more profitable than that of legumes, which add nitrogen to the soil but are somewhat more expensive to use. . . .

"Dextrose gave better results in the azofication experiments than mannit and may, therefore, be substituted for the more expensive material. There was little similarity between the effects of the different organic materials on the different bacterial processes. . . .

"The manures and legumes increased the first crop of oats, except in the case of the horse manure, which apparently exerted an injurious effect on the crop in its early stages of growth. . . . The substances with wide nitrogencarbon ratio decreased the crop yield while those of narrow ratios gave increases. The nitrogen factor was evidently very important on this soil.

"The nitrogen-carbon ratio of the organic materials did seem to be of importance in determining the influence on the first crop of oats. . . . The influence of the various substances applied to the soils was noted on a second crop of oats, but the relative effects were different. The nonlegumes had as great an influence as the legumes, and hence previous conclusions are confirmed that with the use of the former materials sufficient time must be allowed to elapse for azofication to occur if as beneficial effects are to be secured as with legumes. The nitrogen-carbon ratio of the materials applied to the soil did not seem to be of as much importance in determining the effect on the second crop of oats as in the case of the first crop."

The organic matter of the soil.—IV, Some data on humus-phosphoric acid, R. A. GORTNER and W. M. Shaw (Soil Sci., 3 (1917), No. 2, pp. 99-111).—Studies of the phosphoric acid in the humus of soils described in previous reports of this series (E. S. R., 37, p. 20) are reported. These included the determination of the phosphoric acid content of the ammonia extracts of the soils, of peats, and of unchanged vegetable materials both before and after leaching the samples with 1 per cent hydrochloric acid.

It was found that "ammonium hydroxid in 4 per cent concentration will, in certain soil types, extract more phosphoric acid from the air-dry soil than will 1 per cent hydrochloric acid, and in only one sample of eight different soil types did hydrochloric acid extract appreciably more phosphoric acid than did the ammonia. There appears to be no relation between the amounts of phosphoric acid extracted by ammonia from the unleached soil and that extracted after leaching with 1 per cent hydrochloric acid, although in both instances there is usually a greater quantity of phosphoric acid extracted by the ammonia than is extracted by the acid. The amounts of humus-phosphoric acid present in the eight soil types studied when compared with the known fertility of these soil types do not support the theory that a high humus-phosphoric acid content is a necessary factor in soil fertility....

"There is no relationship detectable between the total nitrogen content of the soil and the phosphoric acid extracted by the different treatments. The amount of 'humus ash' present in an ammonia extract is extremely variable, even when the extractions have been carried out under identical working conditions. A minimum of 6.7 per cent and a maximum of 32.6 per cent of ash were found in the 'humus' extracted from the eight mineral soil types studied. Such a wide divergence can be accounted for only by the presence of considerable amounts of clay or absorbed mineral materials. . . .

"The 'humification' of vegetable materials in contact with a mineral soil for an entire year did not increase the humus-phosphoric acid over that contained in the original subsoil. The phosphoric acid present in the ammonia extract of soils can not be correlated either with the amount of organic matter present or with the known fertility of the soil type. Inasmuch as this phosphoric acid does not represent a definite chemical entity, there appears to be no valid reason why determinations of humus-phosphoric acid should be made. It is pointed out that the conclusions drawn in regard to colloidal absorption of phosphoric acid apply with equal force to determinations of humus-potash, that in all probability organically bound potash does not occur in the soil in appreciable amounts."

Twenty-four references to literature bearing on the subject are appended.

Soil survey of Buchanan County, Missouri, B. W. TILLMAN and C. E. DEAR-DORFF (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 46, fig. 1, map 1).—This survey, made in cooperation with the Missouri Experiment Station, deals with the soils of an area of 258.560 acres in northwestern Missouri, which is divided into upland and level flood plain. The upland ranges from hilly to rolling and undulating, and is thoroughly, and in places excessively, drained. The bottom land drainage is generally imperfect. The soils of the county are of loessial, glacial, residual, and alluvial origin.

Including marsh, 15 soil types of 10 series are mapped, of which the Knox silt loam, Marshall silt loam, and Wabash silt loam cover 33.6, 32.6, and 11.8 per cent of the area, respectively.

Soil survey of Polk County, Nebraska, J. M. SNYDEB and T. E. KOKJEB (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 30, fig. 1, map 1).—This survey, made in cooperation with the Nebraska Soil Survey, deals with the soils of an area of 275,200 acres in east-central Nebraska.

"About two-thirds of the county consists of uplands of the loess plain and has a flat to undulating topography. On the north there is an abrupt break from this upland, and a strip of roughly rolling land intervenes between it and the broad valley of the Platte River. The alluvial lands of the valley are generally level or undulating, with local surface inequalities." The upland soils are of loessial origin.

Including riverwash, 16 soil types of 11 series are mapped, of which the Grundy silt loam, a dark brown prairie soil with heavy subsoil, covers 62.9 per cent of the area and is considered the most important soil type in the county.

Soil survey of the Camden area, New Jersey, A. L. Patrick, C. C. Engle, and L. L. Lee (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 45, pls. 5, figs. 3, map 1).—This survey, made in cooperation with the New Jersey Geological Survey and Agricultural Experiment Station, deals with the soils of an area of 449,280 acres in the Coastal Plain in southern New Jersey, the topography of which is level to gently rolling. Drainage is effected by numerous small streams. The soils of the area are derived from beds of unconsolidated sand, sandy clay, gravel, greensand, and marly clay.

Including riverwash and tidal marsh, 26 soil types of 10 series are mapped, of which the Sassafras sandy loam and sand cover 19.1 and 14.1 per cent of the area, respectively. The Sassafras and Collington series cover the greater part of the area.

Soil survey of Blair County, Pennsylvania, J. O. VEATCH, H. P. YOUNG, and H. P. COOPER (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 48, fig. 1, map 1).—This survey, made in cooperation with the Pennsylvania College and Station, deals with the soils of a well-drained area of 341,760 acres in south-central Pennsylvania, the topography of which is in general mountainous and hilly.

The soils of the county are of residual, alluvial, and colluvial origin. Including rough stony land, 23 soil types of 13 series are mapped. "The Dekalb soils are most widely distributed, covering about 29.3 per cent of the area of the county." The most extensive soil type is, however, rough stony land, covering 17.7 per cent of the area, followed in order by the Dekalb stony loam 15.4 per cent, and Upshur stony loam 12.2 per cent.

Summary of results of cane culture tests in Java, I-III, J. M. GEERTS (Meded. Proefstat. Java-Suikerindus., 5 (1915), No. 21, pp. 593-607; 6 (1916), Nos. 6, pp. 139-203, figs. 4; 9, pp. 233-305, figs. 5; Arch. Suikerindus. Nederland. Indië, 23 (1915), No. 52, pp. 1965-1979; 24 (1916), Nos. 14, pp. 473-537, figs. 4; 25, pp. 929-1001, figs. 5).—In part 1 of this series of papers on sugar cane experiments in Java the author presents a general outline of the methods and aims of experimental work with sugar cane, with special reference to fertilizers.

In part 2, comparative studies of ammonium sulphate and boengkil, an organic nitrogenous fertilizer made of crushed oil-containing seeds, as nitrogenous fertilizers for cane are reported.

In general, the better results were obtained with ammonium sulphate. When a part of the sulphate was replaced by boengkil the results were more favorable than when boengkil was used alone. Better results were obtained on light soils with boengkil than on heavy soils. With a fertilization of light soil with boengkil furnis! ing an amount of nitrogen equivalent to 124 lbs. of ammonium sulphate the crop yield decreased about 1 per cent. Fertilization with boengkil was more expensive than with ammonium sulphate.

In part 3, dealing with 41 comparative tests of ammonium sulphate and sodium nitrate on cane, it was found that with reference to yield the advantage lay with the ammonium sulphate to an average amount of 0.73 per cent for cane and 0.24 per cent for sugar. In the 21 tests made on light soil the yields obtained with ammonium sulphate were 1.75 per cent greater for cane and 1.1 per cent greater for sugar. In the remaining 20 tests, made on heavy soil, greater yields were obtained with sodium nitrate to the amount of 0.33 per cent for cane and

0.6 per cent for sugar. No injurious influence of the sodium nitrate on the soil structure was observed.

The greatest difficulty encountered in the use of sodium nitrate was the ease with which it is leached out of the soil. It is considered probable that on heavy soils there was some loss of sodium nitrate through denitrification. For this reason it is considered inadvisable to use stable manure with sodium nitrate on heavy soils. In five tests on light soil the use of stable manure with sodium nitrate or ammonium sulphate had no such injurious results.

In four tests on soil rich in lime, ammonium sulphate gave better results than sodium nitrate. In two tests in which molasses was used with ammonium sulphate and with sodium nitrate, good results were obtained in the former case but not in the latter. In four tests on light and four tests on heavy soils, it was found that ammonium sulphate can be partially replaced by sodium nitrate with profit.

It is considered, therefore, that the advisability of using sodium nitrate as a substitute for ammonium sulphate on Java cane soils will depend mainly on the cost or scarcity of the ammonium sulphate and the cost of sodium nitrate.

The solubility of mineral phosphates in citric acid, II, G. S. ROBERTSON (Jour. Soc. Chem. Indus., 35 (1916), No. 4, pp. 217-220; Chem. News, 114 (1916), No. 2978, pp. 295-298).—Continuing previous work (E. S. R., 33, p. 313), experiments with Makatea Island, Florida pebble, and Algerian, Gafsa, Tunisian, and Belgian phosphates are reported, which led to the conclusions "that mineral phosphates are completely soluble in 2 per cent citric acid if a sufficient number of extracts are made. In the majority of the rock phosphates examined five extracts removed from 90 to 100 per cent of the phosphoric acid present.

"Even a small amount of free lime or calcium carbonate decreases substantially the solubility of mineral phosphates as judged by the citric acid test. When a large amount of calcium carbonate or free lime is present, the citric acid test, as commonly practiced, is a test for lime and not for phosphates. It is important in this respect to distinguish between free lime and calcium carbonate and lime actually entering into the composition of the phosphate. The higher the percentage of lime actually entering into the phosphate compound, the higher the citric solubility of the phosphate Fineness of grinding affects the total citric solubility of the mineral phosphates (judged by five extracts) to the extent of approximately 10 per cent decrease for each of the gradients—passes '100,' refuses '100,' refuses '60,' and refuses '30' sieve. With one exception, calcining produces a marked decrease in the citric solubility of mineral phosphates. The longer the calcining continues, the more insoluble does the phosphate become."

The results as a whole are taken to indicate the worthlessness of the citric acid test as a means of judging the relative fertilizing values of phosphatic manures. Mineral phosphates are considered as valuable as a source of phosphoric acid for plants as basic slag.

Liming and lime requirement of soil, J. W. Ames and C. J. Schollenberger (Ohio Sta. Bul. 306 (1916). pp. 281-396, figs. 5).—The work of others bearing on the subject is briefly reviewed, and data obtained from several years' study of fertility plats under various conditions of liming and treatment and the results of certain pot experiments are reviewed and summarized.

It was found that "the chemical composition and mechanical condition of lime materials are probably of primary importance in relation to speed of reaction with soil, rate of loss, and usefulness as soil amendments. The comparatively small amounts of carbonate residual from applications of various lime materials after relatively brief periods indicate that the speed of reaction

with soil of commercial lime materials is of a high order. From data obtained for a silt loam soil quite deficient in basic material and receiving different amounts of ground limestone under normal conditions, it can be considered that under similar conditions 70 per cent of the calcium supplied by a moderate application of limestone—say 2 tons per acre—will have left the carbonate form within a year. From heavy applications—6 to 13 tons per acre—the percentage of calcium and magnesium combining with the soil and the proportion carried downward and lost are less when referred to the total amount applied, but, expressed as pounds per acre, the quantities are really greater than those from smaller applications. . . .

"With regard to the effect of fertilizer treatment upon carbonates residual from applications, it was found that ammonium sulphate was capable of accelerating the decomposition of carbonates, and is the only fertilizer in common use the effects of which in this direction are unmistakably apparent. In distinction from ammonium sulphate, a physiologically acid salt, sodium nitrate, a physiologically alkaline salt, appears to have a general tendency toward the conservation of carbonates."

Manure appeared to exert an influence toward the conservation of carbonates. Of the bases added and not accounted for by the presence of carbonates, a considerable proportion was retained by the first 12 in. of soil. The unfertilized plats retained much less than the average of the fertilized. The differences in amounts of bases retained in forms other than carbonate by the fertilized plats were not great. The soil of the lime extension plats to which were applied 6 and 13 tons of limestone per acre with and without manure retained more calcium and magnesium in the first 12 in. than the soils from five-year rotation plats, although not by any means a proportionate amount. The bases retained were mainly in the first 8 in., but increases were apparent as deep as the samples were taken (24 in.). The manure appeared to have caused increased fixation of calcium by the soil and to have had a tendency toward equalizing its distribution in the several depths sampled. Leaching was the most important source of loss of carbonates and basic calcium.

Very coarse limestone (1/3 to 1/20 in.) is probably of little value unless applied in excessive amounts. In general, dolomitic stone ground to different degrees of fineness and applied to the soil suffered a less degree of decomposition than corresponding applications of a higher calcium stone. Crop yields from small plats gave no consistent indications of superiority for either form of stone. Soils containing water-soluble acid constituents in determinable quantity were rarely encountered.

"The litmus paper test, when carefully conducted and intelligently interpreted, is probably as good as any chemical test for the determination of the soil's need of lime. All the lime requirement methods tried indicated marked differences between limed and unlimed soil of the same character and treatment, and all, except the Veitch method, loss in bases due to a long period of cultivation.

"The data available indicate that the vacuum method is the best adapted of the procedures tested for use as a quantitative method in studying the relations between the soil and its supply of bases. There is no evidence that any of the lime requirement methods tested furnishes reliable indications as to the optimum rate of application for field practice. For the several soils investigated, there was found to be an approximately quantitative relationship between the bases soluble in fifth-normal nitric acid (excluding carbonates) and differences in lime requirement by the vacuum method.

"Acidity of soil, as the term is usually employed, is a negative property; that is, due to qualities inherent in all soils, but manifested only by those

deficient in basic constituents. Too much emphasis has been laid upon soil acidity, and the more important theme, soil basicity, has been neglected.

"Calcium and magnesium are retained in the soil mainly as silicates, possibly partly in combination with organic matter.

"Field tests show that the yields of clover on plats treated with acid phosphate have been less than on plats where bone meal and basic slag were used as carriers of phosphorus. The evidence obtained by laboratory studies, however, does not indicate that acid phosphate has any important influence toward the depletion of the soil's supply of bases; effects due to the acid nature of this fertilizer are insignificant when compared with those attributable to the use of ammonium sulphate.

"Dried and green crop residues mixed with soil did not increase its lime requirement as determined in the laboratory. Field observations and tests made do not indicate that organic matter furnished by green crops causes acidity in soil. A mulch of fermenting material (apple pomace) caused the lime requirement of the soil beneath to be increased. Sawdust similarly used had little effect.

"Pot experiments indicate that the base of various silicates, including blastfurnace slag, may be of benefit to crop growth.

"Lime requirement determinations on samples taken at various depths of a limed soil indicate that the effect of lime applied is perceptible to a depth of 24 in, or more.

"Unusual weather conditions to which the soil may have been exposed in the field have had no great effect upon the lime requirement as determined in the laboratory."

Effect of some manganese salts on ammonification and nitrification, P. E. Brown and G. A. Minges (Iowa Sta. Research Bul. 35 (1916), pp. 3-22).—Experiments on the effects of manganese sulphate, manganese chlorid, manganese nitrate, and manganous oxid in varying amounts on the ammonification of dried blood and the nitrification of ammonium sulphate in a clay-loam soil are reported.

It was found that "manganese chlorid, in applications greater than 2,000 lbs. per acre, depressed both ammonification and nitrification, the depression increasing as the size of the application was increased until a point was reached at which both processes ceased. With smaller amounts of the chlorid the effects on the two processes were not identical, but tended in the same direction. Thus the applications of 100 and 200 lbs. per acre gave increases which were slight in the case of ammonification, but quite distinct in the case of nitrification. With amounts greater than 200 lbs. per acre and less than 2,000 lbs., however, ammonification was depressed while no appreciable depression was apparent on nitrification.

"Manganese sulphate, when applied to the soil at the rate of 100 lbs. per acre, increased appreciably both ammonification and nitrification. In amounts greater than 100 lbs. per acre and less than 2.000 lbs., ammonification was increased, but to a less extent than with the 100-lb. application, but with nitrification no gains nor depressions were found with these amounts. In applications equal to or greater than 2,000 lbs. per acre nitrification and ammonification were depressed by manganese sulphate, the depression increasing with the size of the application.

"Manganse nitrate added to the soil at the rate of 500 lbs. per acre, or in greater amounts, depressed both ammonification and nitrification, the depression increasing as the size of the application was increased. Manganous oxid, when applied to the soil at the rate of 2,000 lbs. per acre or in larger quantities,

depressed both ammonification and nitrification, the depression becoming greater as the size of the addition was increased."

It is concluded that "if manganese salts in small quantities increase crop yields on a soil, that increase may be due in part at least to a beneficial effect on ammonification and nitrification with a consequently greater production of available plant food. On the other hand, if manganese salts when applied to the soil restrict crop growth, that restriction may be due in part to a depression of bacterial activity."

Fertilizer analyses, H. B. McDonnell et al. (Md. Agr. Col. Quart., No. 75 (1917), pp. [31]).—This contains the results of actual and guaranteed analyses of 505 samples of fertilizers and fertilizing materials offered for sale in Maryland from August, 1916, to January, 1917, inclusive, together with the text of the Maryland fertilizer law.

Commercial fertilizers, 1916, B. H. HITE and F. B. Kunst (West Virginia Sta. Insp. Bul. 5 (1917), pp. 3-85).—This bulletin contains the results of actual and guaranteed analyses of 477 samples of fertilizers and fertilizing materials offered for sale in West Virginia during 1916.

# AGRICULTURAL BOTANY.

The morphology of the monocotyledonous embryo and of that of the grass in particular, W. C. Worsdell (Ann. Bot. [London], 30 (1916), No. 120, pp. 509-524, figs. 10).—The author, concluding a study of Zea mays, Hordeum vulgare, and other monocotyledonous plants, states that the scutellum is the lamina of the cotyledon, corresponding to that of the foliage leaf in grass. The part of the cotyledon which corresponds to the sheath of the foliage leaf becomes obscured after the early stage of its development. The coleoptile appears to be that part of the cotyledon which is represented in the foliage leaf by the ligule. The epiblast is that part of the cotyledon corresponding to the auricles of the base of the lamina of the foliage leaf in certain grasses.

The cotyledon of the grasses differs in no essential, however, from that of other monocotyledons. The mesocotyl is the elongated primary node. The position of the cotyledon is terminal in all monocotyledons, being the continuation of the hypocotyl. The balance of development of the cotyledonary lamina and sheath may vary in favor of the latter in certain cases and stages. In certain instances the sheath may develop into a second cotyledon, this character being novel and progressive instead of ancestral and reversionary.

Further experiments on correlation of growth in Bryophyllum calycinum, J. Loeb (Bot. Gaz., 62 (1916), No. 4, pp. 293-302, flgs. 17).—Further observations (E. S. R., 34, p. 730) under varied conditions are reported. These show that there is in a detached leaf, or pair of leaves, and adjacent portions of a cutting of Bryophyllum, a suction (this term serving as a symbol to denote the direction of the flow of materials) associated with the growth of a marginal or axial bud, which inhibits growth in neighboring portions. The experiments show that a vigorous growth in the notches of a leaf may act as a center of suction which may prevent the flow of sap to the cortex, and thus inhibit growth there if the suction by the stem, or in this case the cortex, is not so strong.

Cambial activity in certain horticultural plants, L. Knudson (Bul. Torrey Bot. Club, 43 (1916), No. 10, pp. 533-537).—Recording in tabular form studies regarding the season of cambial activity in woody plants, the author states that cambial activity began in the peach at the time of the opening of the buds. This is contrasted with the result of observations on the larch, grape, and

apple. Observations on other trees are also noted. No evidence was obtained to show that the formation of phloëm continued later than that of xylem.

The epidermal cells of roots, EDITH A. ROBERTS (Bot. Gaz., 62 (1916). No. 6, pp. 488-506, figs. 17).—This attempt to determine the varying factors within and without the epidermal cell of the root and their reciprocal relations was prompted by the fact that frequently the presence or the absence of root hairs is used as an indicator of changed external conditions.

It is stated, as the result of study with various plants, that the formation of a root hair is first indicated by the swelling of the outer wall of the epidermal cell. This is due to the fact that the physical resistance of the wall is overcome by the osmotic pressure within the wall, continued swelling and growth occurring in a region of comparatively slight resistance which has no apparent relation to the position of the nucleus. The wall of the root hair is composed of an inner cellulose membrane and an outer membrane of calcium pectate, soil particles being held to the layer by pectin mucilage, these facts accounting supposedly for the high absorbing efficiency of the root hairs.

New determinations of permeability, S. C. Brooks (*Proc. Nat. Acad. Sci.*, 2 (1916), No. 10, pp. 569-574, figs. 6).—The author reports determinations of permeability of plant tissues by a new method claimed to be independent of methods or improvements thereof, as previously employed. The results are said to agree in showing that living protoplasm is normally permeable to the salts employed, but that salts in solution may alter permeability. Some (as sodium chlorid) cause an increase, others (chlorids of calcium, lanthanum, and cerium) a decrease followed by an increase, the permeability remaining normal in a balanced solution.

Studies on exosmosis, S. C. Brooks (Amer. Jour. Bot., 3 (1916), No. 9, pp. 483-492, figs. 4).—The author has made a study on the tendency of osmotically active substances to diffuse out of the cell in the course of experiments where turgidity or osmotic pressure is used as a criterion of permeability. Strips from scapes of dandelion were used in experiments in which the exosmosis of electrolytes into distilled water from such strips was determined after their treatment with distilled water or solutions of the chlorids of sodium, calcium, or cerium.

It was found that sodium salts increase, while calcium salts decrease, the rate of exosmosis of other electrolytes from the protoplasm of *Taraxacum officinale*. It is possible to prepare a solution such that, when it is used at a concentration isotonic with the protoplasm, it causes no perceptible alteration in the permeability of the plasma membrane.

The rôle of osmotic pressure of a soil solution in the culture of wheat, N. M. Tulaĭkov (Toulaikoff) (Zhur. Opytn. Agron. (Jour. Agr. Expt.), 17 (1916), No. 2, pp. 122-164, figs. 9).—The osmotic pressure of the soil solution is considered of great importance in the development of wheat, manifesting itself at germination and at every other important period in the life of the plant. Some particulars are given regarding observed modifications of the relations between the grain and the stalk produced. These may be made to deviate considerably from the normal or observed tendency in the direction of a desired optimum.

The structure of the bordered pits of conifers and its bearing upon the tension hypothesis of the ascent of sap in plants, I. W. Bailey (Bot. Gaz., 62 (1916), No. 2, pp. 133-142, pl. 1, figs. 2; abs. in Jour. Roy. Micros. Soc. No. 6 (1916), p. 572).—The author claims to have shown that in case of Larix and Sequoia the pit membranes are supplied with perforations of various forms, generally elongated, and of sizes varying from 0.5  $\mu$  to 3  $\mu$ , but the detailed structure of which is obscured by the overhanging and thickened pit borders. It

is stated that aqueous solutions containing fine particles can be passed through the membranes of the bordered pits of sapwood from the stems of these and other conifers, also that gases can be readily forced through bordered pits thoroughly saturated with sap. The surface tension of sap in the pit membranes can in some cases, it is claimed, be overcome by pressures of less than 3 atmospheres. This is thought to disprove the tension hypothesis, according to which a tension of from 5 to 20 atmospheres is required to maintain continuous columns of water in trees.

Relation of transpiration to assimilation in steppe plants, V. S. ILJIN (Jour. Ecology, 4 (1916), No. 2, pp. 65-82).—The author, reporting in considerable detail on another phase of the work previously noted (E. S. R., 33, p. 628), claims that the experiments herein described show simply that we may expect to find in drought-resistant plants a more economical evaporation of water.

Recent developments in the study of endotrophic mycorrhiza, M. C. RAYNER (New Phytol., 15 (1916), No. 8, pp. 161-175).—This is a review of recent studies and views on endotrophic mycorrhiza and a discussion of their bearing on current conceptions of the physiology of the relationship and of their significance in experimental ecology.

The view held by the author is that the phenomenon of mycorrhiza in plants is only an expression of the warfare waged continually by all organisms against parasitic invasion of their tissues. The flowering plant possessing mycorrhiza not only has checked the invading fungus, but has turned the invasion to its own advantage.

Studies in the physiology of the fungi.—I, Nitrogen fixation, B. M. Duggar and A. R. Davis (Ann. Missouri Bot. Gard., 3 (1916), No. 4, pp. 413-437).—This is the first report of a series of several studies now in progress on the physiology of the fungi. Tabular details are given of the results obtained from a study of nitrogen fixation. This was not established for Aspergillus niger, Macrosporium commune, Penicillium digitatum, P. expansum, and Glomerella gossypii, but cultures of Phoma betw on mangel and on sugar beet decoction with sugar showed a nitrogen gain, which is considered to prove definitely that nitrogen fixation occurs. Comparative studies of Azotobacter strains indicate the usual relatively large fixation of nitrogen by that organism.

Studies in the physiology of the fungi.—II, Lenzites sepiaria, with special reference to enzym activity, S. M. Zeller (Ann. Missouri Bot. Gard., 3 (1916), No. 4, pp. 439-512, pls. 2).—This article, continuing the series indicated above, is an account with discussion of studies on the wood-destroying fungus, L. sepiaria, as regards the behavior of this fungus when grown in pure cultures on selected media. The fungus grows well on 50 per cent resin by weight (which is said to be a proportion greater than that found in any coniferous wood), and growth is not entirely inhibited by 85 per cent resin.

The metabolism of the fungus was studied through the agency of enzym action, and this study is reported in some detail. A comparative study of enzyms found in the sporophores and mycelium indicated that the important metabolic processes are carried on chiefly in the vegetative organs in the case of diastase, invertase, tannase, and cellulase, while the oxidases show greater activity in the sporophores.

The mitochondrial origin of rhodoxanthin, F. Moreau (Bul. Soc. Bot. France, 62 (1915), No. 4-6, pp. 158-160).—Discussing observations made by himself and other investigators, the author claims that rhodoxanthin may originate in a plastid or in a chondriosome without passing through a chlorophyll stage. It is thought that mitochondria and plastids may fix certain substances which they select from the protoplasm. These they transform later into products, which may themselves be transitory or final, by means of modifica-

tions in which the phenomena of oxidation and reduction play a leading or at least an important part.

The presence, distribution, and rôle of arsenic and manganese in plants, F. Jadin and A. Astruc (Rev. Sci. [Paris], 54 (1916), II, No. 19, pp. 589-593).—Summarizing the more general results of recent and former investigations (E. S. R., 32, p. 628), the authors state that all the organs of all plants analyzed by them showed the presence of both arsenic and manganese. The former was present in rather small proportion in a number of plants named, and the latter in larger proportion in a few. The chlorophylliferous portions generally contained more than the subterranean parts, and the content of the leaves varied sensibly with age.

No preponderant influence is exerted by the soil content of arsenic or manganese on the percentage of those substances found in the plants, which take what they require, even, if necessary, through the medium of the plants on which they are parasitic. Vegetable foods constitute, if not the only source, at least one of the most important of the sources of the manganese and arsenic normally found in animal tissues.

The authors conclude that arsenic and manganese are of the greatest importance in the vegetable cell, the former exerting an influence comparable to that of phosphorus, the second favoring the oxygen reactions in the plant.

Specific action of barium, W. J. V. OSTERHOUT (Amer. Jour. Bot., 3 (1916), No. 9, pp. 481, 482).—The author briefly describes experiments with Spirogyra in which the chloroplasts were characteristically contracted toward the center of the cells when the filaments were subjected to 0.0001 molecular solution of barium chlorid. This action is considered specific for barium, no other salt examined producing this effect at such dilutions.

The plant as an index of smoke pollution, C. Crowther and A. G. Ruston (Abs. in Rpt. Brit. Assoc. Adv. Sci., 85 (1915), p. 780).—The results are reported of experiments and observations during several years on the types of vegetation injured by smoke, the general appearance of plants so injured, and the specific effects of smoke on plants.

The authors state that where smoke is excessive trees and shrubs make only a stunted growth. Bulbous and seed-bearing plants are sensitive to smoke, confers particularly so. Hawthorn barely persists in such areas, leguminous plants rapidly disappear, and coarse grasses and weeds monopolize meadows and lawns, while rhubarb is very little or not at all affected, and elder grows successfully in such regions.

Destruction of buds and young shoots is noticeable. Characteristic discoloration of leaves occurs and the leaves fall earlier than normally. Colors are weakened, blues and reds tending to white and bronzes to pale yellow, and certain definiteness of correlation appears between depth of tinting and smoke pollution. The choking of stomata by soot particles has been observed to occur. Crop yields are lowered by excess of smoke, and development of root structures is found to be retarded. A relatively high content of chlorin, of arsenic, and especially of sulphur in nonprotein forms in plants is observable.

Seeds in smoke-polluted areas show decrease as regards size, weight, germination capacity, and germination energy. Inhibitory effects upon enzym activity have been demonstrated by comparative measurements of the activity of oxidase, catalase, lipase, and emulsin.

Teratology in iris flowers, ELEANORA ARMITAGE (Gard. Chron., 3. ser., 60 (1916), No. 1557, p. 203).—Abnormalities relating to the number, shape, arrangement or fusion of floral parts are noted as occurring in different species and varieties of iris.

New dimorphic mutants of the Enotheras, H. Devres (Bot. Gaz., 62 (1916), No. 4, pp. 249-280, figs. 5).—A study has been made of the genetic behavior of E. scintillans, E. cana, E. pallescens, E. lactuca, and E. liquida, mutants of E. lamarckiana. Each of these in every generation, under ordinary circumstances, splits into nearly equal groups of the mutant type and of the parent type, the E. lamarckiana offspring being nearly constant in their progeny. Besides the two main types each usually produces a relatively high percentage of other mutants. The parental types appear on an average in about 40 per cent (on very strong biennials as much as 97 per cent), the other 60 per cent (or less) being E. lamarckiana mutants, these figures varying with cultures or with individuals. Dimorphic mutants of this type also occur in allied species of the biennis group. In dimorphic mutants the special characters are inherited through the ovules, but not, so far as known, through the pollen, which appears like that of pure E. lamarckiana.

The dimorphic mutants constitute a group in which the hereditary phenomena are evidently independent of the external visible characters of the special members of the group, but are assumed to have the same intrinsic causes in the different cases.

Sterility as the result of hybridization and the condition of pollen in Rubus, C. S. Hoar (Bot. Gaz., 62 (1916), No. 5, pp. 370-388, pls. 3).—The author gives a brief review of previous work and information regarding pollen sterility and related phenomena, with an account of work done by himself in 1915 on some 40 species of Rubus, from which mature pollen grains were obtained for utilization in study by a method which is described. He also details the percentages obtained of pollen found to be sterile in different degrees in many of the species.

It is stated that pollen sterility is a common character throughout the entire genus. This is thought to typify a condition prevailing in many angiosperms, among which are found many forms appearing as natural hybrids between distinct species and exhibiting more or less blending of characters rather than Mendelian segregation. Rubus hybrids formed between distinct species are almost entirely sterile, while crosses of closely related and supposedly more compatible varieties may give almost no indication of a hybrid origin.

## FIELD CROPS.

Report of the agronomy division, C. A. SAHR (Hawaii Sta. Rpt. 1916, pp. 26-31, pls. 2).—This reports a continuation of work previously noted (E. S. R., 35, p. 527).

The 1916 spring rice crop on the nonaerated plat fell 51 per cent below the yield of the same plat in 1915, but outyielded the aerated plat by 490 lbs. of rice paddy, or 18.7 per cent.

Early Rose outyielded Burbank and American Wonder in potato variety tests at the Tantalus substation (elevation 1,000 ft.). In culinary tests of these varieties the Burbank proved superior in mealiness and flavor.

Cultural trials of *Phaseolus aconitifolius*, *Crotalaria candicans*, *Desmodium hirtum*, and several clovers are briefly noted. The average yields of green forage per acre for the red clovers were as follows: Red clover from Switzerland (S. P. I. No. 37939) 8.55 tons, ordinary red clover (F. C. I. No. 1472) 8.45, Swiss Rummellee clover or apitrefle (S. P. I. No. 37937) 2.1, and red clover from Switzerland (S. P. I. No. 37938) 1.8 tons. Alsike clover gave a yield of 6.15 tons per acre. Ordinary white clover (S. P. I. No. 34930) made appreciably more growth than wild white (S. P. I. No. 38579) and Ladino

white (F. C. I. No. 1482). *Trifolium striatum* (F. C. I. No. 1450) succumbed to drought in the summer of 1915, while *T. dubium*, replanted in April, 1915, produced a good stand and was maturing seed in July, 1916.

Tests of five varieties of winter rye, two of oats, and one of winter barley for grain and forage were begun in December, 1915. Mexican winter was the only rye variety headed out at the time of this report. The results of the oat tests indicated yields of from 13 to 22 bu. Winter barley failed to head out. A second planting of five varieties each of oats, barley, and rye, and three varieties of wheat was made in March, 1916. Fulghum oats was the first variety to head out, with Smyrna the first barley variety.

Kafir corn, mile maize, and feterita were grown in connection with Sugar Drip sorghum for a comparison of yields of grain and forage. The yields of grain per acre were 66.5, 436, 235, and 689 lbs., and of forage per acre, 6, 4.52, 6.65, and 11.27 tons, respectively. Tests of other grain sorghums are noted.

New long-period tests for yields of forage were begun in August, 1915, with nonsaccharin sorghum No. 309 and Japanese cane. The latter was propagated partly by division of the roots and partly by cuttings of the cane. The first cutting for forage was made December 29, and the estimated acre yield of the stand from cuttings totaled 2 tons more than that from the division of roots.

Andropogon nodosum, A. seriecus, A. saccharoides, Tricholana rosea, and Giant Bermuda grass are listed as the best five drought-resistant pasture grasses for low and medium elevations. Brief notes are given on numerous other grasses and of a test of rape.

Spraying Japanese nut grass with arsenite of soda when the grass is in full bloom continued to be the most effective control measure. Plowing with a disk plow at intervals of four or five weeks during exceedingly dry periods greatly reduced the vitality of the tubers.

Report of [field crop work at] the Glenwood substation, J. B. Thompson (Hawaii Sta. Rpt. 1916, pp. 40-42, pl. 1).—Paspalum dilatatum has been subjected to a number of field tests in an effort to obtain a suitable forage crop for dairy cattle to supplement Commelina nudiflora and Panicum barbinode by producing a heavy winter growth. Paspalum dilatatum having been associated with stock poisoning in the Southern States (E. S. R., 34, p. 676), extreme precautionary measures are deemed necessary in introducing the plant into the dairy regions.

Volunteer plants of California bur clover were observed to make a rank and rapid growth between December and April, and trial plantings of this crop will be made during the coming winter season.

Edible canna (Canna edulis) was planted in December, 1914, in an attempt to secure a local product suitable for hog feed. A yield at the rate of approximately 31.5 tons per acre was harvested in January, 1916. Further tests of this crop are in progress. A portion of the harvested crop stored in ordinary bags showed practically no loss from decay for a period of three months. The chemical composition of the fleshy rhizome is said to be closely comparable to that of the Irish potato.

Jerusalem artichokes (*Helianthus tuberosus*) were also grown as a hog feed, and yielded at the rate of approximately 11 tons per acre from a stand estimated at only 33½ per cent at the time of harvest. The artichoke was completely ruined by a moldlike fungus when stored in bags, although roots remaining in the ground were in a perfect state of preservation over two months after the bulk of the crop was harvested.

The possible Wayne County farm, C. E. THORNE (Mo. Bul. Ohio Sta., 2 (1917), No. 3, pp. 96-98).—Comparing statistics of acreage and yield on the average Wayne County farm and on the experiment station farm at Wooster,

it was found that on an area of 46.3 acres the average Wayne County farmer produced annually crops valued at \$764, while on an area of 40 acres of representative soil at Wooster the value of the same crops had amounted to \$1,251 per annum. The additional expenditures for fertilizers, lime, and labor are estimated at \$197, which is thus returned with a dividend of \$287, or 140 per cent.

It is concluded that by reducing the acreage in crops and concentrating time and energy on a smaller area of the best land, two-thirds of the area now cultivated in the county might be made to produce all that is now grown within the county, and at a saving in labor which would more than pay for the fertilizers required.

The residual effect of fertilizers and manure, C. E. THORNE (Mo. Bul. Ohio Sta., 2 (1917), No. 2, pp. 48-50).—Supplementing a report previously noted (E. S. R., 36, p. 829), average results obtained in crop-rotation experiments extending over a period of 23 years show that from one-third to one-half the total effect of fertilizers and manure is carried forward to the crops following the one receiving the treatment. The results are summarized in the following table:

Residual effect of fertilizers and manure.

Rotation.	Period of experi- menta- tion.	Treatment and crop to which applied.	Increase per acre.			
			Weight.		Value.	
			Fertil- ized crops.	Residu- ary crops.	Fertil- ized crops.	Residu- ary crops.
Corn, oats, wheat, clover, and timothy.	Years. 23	Chemical fertilizer applied to wheat. Chemical fertilizer approximately.	Per cent. 51	Per cent. 49 35	Per cent. 56	Per cent. 44
Do	23 18 14	plied to wheat and corn.  Manure applied to wheat and corn.  Manure applied to corn  Fertilizers and manure applied to tobacco.	52 47	48 53	64 55 70	36 45 30

The effect of soluble nitrogenous salts on nodule formation, E. B. Fred and E. J. Graul (Jour. Amer. Soc. Agron., 8 (1916), No. 5, pp. 316-328).—This paper gives the results of some investigations of soluble nitrogenous salts and their effect on nodule formation. The plan of the experimental work included the following points of investigation: (1) The effect of ammonium nitrate on nodule formation in sand, (2) the effect of calcium nitrate on nodule formation in a mixture of soil and sand, (3) the effect of sodium nitrate and ammonium sulphate on alfalfa and crimson clover in Miami silt loam, and (4) the effect of accumulated nitrates in various soils on nodule formation.

\* From the data secured it seems evident that under field conditions nitrates rarely, if ever, occur in amounts sufficient to prohibit nodule formation. It is probable, however, that the percentage gain of nitrogen in legumes is injured by the presence of soluble nitrogen. The nitrogen assimilating power of legumes in the presence of soluble salts appears to depend upon many factors, such as the physical, chemical, and biological composition of the soil, species of plant, etc. An abundant moisture supply may be beneficial to nodule formation in two ways, (1) water is necessary for the normal function of the plant and bacteria, and (2) water tends to leach out the soluble nitrogen. As a general conclusion it may be said that, in order to secure a maximum growth as well

as a maximum gain of nitrogen from legumes, a small amount of soluble nitrogen is beneficial while large amounts are detrimental.

A brief bibliography is given at the end of the article.

Seeding small grains, C. G. WILLIAMS (Mo. Bul. Ohio Sta., 2 (1917), No. 3, pp. 76, 77).—Limited seeding experiments are reported with 8-in. and 4-in. grain drills.

An average of two years' tests with oats shows yields of 49.19 and 45.48 bu. of grain and 3,020 and 3,080 lbs. of straw per acre for the 8-in. and 4-in. drills, respectively. In tests with wheat in 1915, using a 6.5 and 4.5 pk. rate of seeding, the respective yields for the 8-in. and 4-in. drills were 28.71 and 28.37 bu. of grain and 3,247 and 3,487 lbs. of straw.

[Field crops] (Rev. Indus. y Agr. Tucumán 7 (1916), No. 1-2, pp. 5-59, figs. 16).—Extensive notes are given on sugar cane culture, together with brief notes on maize, sorghum, cowpeas, and peanuts, in the Province of Tucumán.

[Field crops] (Jaarb. Dept. Landb. Nijv. en Handel Nederland, Indië, 1914,  $pp.\ VI+331,\ pls.\ 16$ ).—This is a general administrative report of the work conducted at the various experimental centers of the Dutch East Indies.

The cultivation of dry land, R. Escobar (Estac. Agr. Expt. Ciudad Juárez, Chihuahua, Bol. 47 (1914), pp. 97, pls. 26).—This is an extensive publication upon dry land farming in Mexico. The meteorological and soil conditions are discussed in detail. Implements for dry land cultivation are described and illustrated. Brief notes are given on a number of crops recommended for growing in these regions, the most important of which are sorghum, beans, corn, wheat, cotton, potatoes, peanuts, alfalfa, sweet potatoes, and canaigre.

Field culture tests on peaty soils in 1915, H. von Feilitzen (Svenska Mosskulturför, Tidskr., 30 (1916), No. 3, pp. 221-235).—The experiments here described were conducted in different sections of Sweden.

The use of lime on various kinds of peaty soils gave quite diverse results, due to varying soil conditions. Where the soil was well supplied with lime, further lime applications remained without effect. In a test on soil with an insufficient lime content the influence of lime applications was still observable seven years later.

Yearly applications of fertilizer on pasture lands of this type were found much more profitable than applications made from time to time. While the best results on all fields were not secured from the same application, it was found in general that it was best to use 100 or 200 kg. of superphosphate, or 300 kg. of Thomas slag, together with 100 or 200 kg. of potash salt per hectare. The residual effect of nitrate of soda on grassland, even on soil of high nitrogen content, was quite marked, which is considered as possibly due to insufficient nitrification of the soil under ordinary conditions. Barnyard manure used for oats also showed residual effects in one section, while in another it was practically without effect after the first year. The increase in the yields of root crops from the use of barnyard manure and fertilizers, which was considerable, seemed to be determined by the excess of commercial fertilizers over barnyard manure.

The two varieties of oats giving the best results in this connection were Gold Rain and Victory. The yield of green forage was generally quite satisfactory, while the yield of root crops was under the average. Of three varieties of rape Munich proved the best. The yields of grass were also satisfactory where frost did not interfere.

[Culture experiments on moor soils at Flahult and Torestorp, Sweden], H. von Feilitzen (Svenska Mosskulturför. Tidskr., 29 (1915), No. 6, pp. 441-473, figs. 4; 30 (1916), Nos. 1, pp. 51-72; 2, pp. 119-159, figs. 6).—The results of experiments here described showed that the beneficial effect of mixing

sand with the surface of insufficiently decayed moor soil was still discernible four years later, and that the treatment had paid for itself with the third harvest. The use of sand on moor or peat soils, either by working the sand into the surface or covering the soils, also gave generally good results. Lime applied to this type of land affected different crops quite differently, the greatest increases in yield apparently due to the treatment being secured with flax and rape followed by barley, red clover, and horse beans.

Fertilizer experiments on low, peaty soil showed a residual effect of barnyard manure the third year after its application and also indicated the greater value of spring application as compared with fall application. Liquid manure applied on moor soil meadows in quantities furnishing approximately 23.4 kg. of nitrogen per hectare (20.8 lb. per acre) increased the yield of hay 1,306 kg. per hectare. Analyses of the liquid manure made at different times brought out a definite relation between its specific gravity and its nitrogen content and consequent manurial effect.

Nitrate of soda and sulphate of ammonia, used in growing rape on a sandy soil, gave practically equal results. Common salt applied in addition to the sulphate of ammonia remained without effect. On a good, peaty soil different quantities of nitrogenous fertilizers gave no increase, while of the phosphatic materials tested Thomas slag proved most effective and superphosphate and bone meal were of about equal value. Of different potash fertilizers 20 per cent potash salt gave a slightly higher increase than kainit, or 37 per cent potash salt, but the dry matter content was highest in the crop grown with the last-mentioned substance and lowest in the crop receiving the kainit. When increasing amounts of the different plant food sources were used it was found that nitrogenous fertilizers in no case paid for themselves, while among the applications of phosphorus the use of 120 kg. of phosphoric acid, equivalent to about 600 kg. of superphosphate, per hectare was most economical and in the potash series the use of 150 kg. of potash, or about 400 kg. of 37 per cent potash salt, gave the highest return.

Of different crops tested for a number of years in this connection, the following varieties gave the best yield: Petkus, Swedish Gray, and Midsummer rye; Plymage and Svanhals barley; Gold Rain, Dala, and Brown Moor oats; Sand, Glenoe, and Solo field peas; Gertrude, Lucia, Moor Rose, and Jewel potatoes; and Bortfeld rape. Notes are also given on drainage experiments and the culture of potatoes.

Time of sowing and harvesting green forage crops on lowland moor soil, J. Lende-Njaa (Meddel. Norske Myrselsk., 14 (1916), No. 3, pp. 85-108).—Oats and peas were sown in the proportion of 2:1 by weight on May 1, 15, and 30, and harvested at the beginning of blossoming, 15 days later, and when the oats were mature. The results secured, together with the chemical composition of the material harvested at the different stages of growth, are tabulated in detail and discussed.

The results indicated in general that a mixture of oats and peas for green forage, in order to make the heaviest and best growth, should be sown as early as possible. The best time of harvesting was found to be about two weeks after the oats began blossoming. The quantity of green forage continued to increase after this period, but the increase did not compensate for the loss in quality which was quite evident in the latest sowings.

Botanical composition of a 20-year-old moorland meadow, A. Mentz (*Hedeselsk. Tidsskr., No. 10 (1916), pp. 127-134*).—The method of seeding this meadow in 1895 is described, together with the fertilizer treatment given during the period. The seed mixture used per töndeland (1.36 acres) was as follows: Red clover 3 lbs., alsike clover 5 lbs., white clover 2 lbs., Italian rye

grass 2 lbs., timothy 5 lbs., meadow foxtail 8 lbs., orchard grass 2 lbs., and roughstalked meadow grass 3 lbs. After 20 years the flora of the meadow was composed of 22.56 per cent of cultivated grasses, 44.97 per cent of wild grasses, 16.43 per cent of leguminous plants, and 12.95 per cent of weeds.

The culture of Bengal grass, teosinte, and Sudan grass, E. SCHIMMEL (Teysmannia, 27 (1916), No. 3, pp. 169-191, figs. 5).—Rather detailed notes are given on the cultivation and yield of Bengal grass, together with brief notes on teosinte and Sudan grass.

Wild fodder grasses, W. Burns (Dept. Agr. Bombay, Ann. Rpt. Expt. Work Ganeshkhind Bot. Gard., 1914-15, pp. 29-31).—A list of 32 wild fodder grasses native to the Poona District, India, is given, together with brief notes on the yields and dates of harvesting.

Carrots and turnips as catch crops, H. Vendelmans (Jour. Bd. Agr. [London], 23 (1916), No. 4, pp. 366, 367).—This is a brief note on the use of carrots and turnips as a catch crop after wheat in Belgium. The carrots are sown broadcast in the wheat just before it heads out, and thus become well established before the wheat is harvested. The turnips are sown immediately after the wheat harvest.

Bean culture, A. L. STRAUSZ (Washington Sta. Popular Bul. 111 (1917), pp. 4).—A popular treatise on the climatic and soil requirements, culture, and harvesting of beans.

Early studies in the selection of Trifolium incarnatum and of the medicagos, E. DE CILLIS (Ann. R. Scuola Sup. Agr. Portici, 2. ser., 12 (1914), pp. 721-726).—This is a brief review of the early improvement of crimson clover and certain of the medicagos, with special reference to their cultivation for forage.

Improvement of red clover, J. Beverley (Jour. Agr. [New Zeal.], 12 (1916), No. 4, pp. 293, 294, fig. 1).—This is a brief note on a red clover single-plant selection, five years old, in August, 1915. Two hundred and seventy flowering-stem growths have been removed from the parent plant and set out in 3-ft. rows. The parent plant gives a large kidney-shaped good-colored seed. About 1,000 seedlings have been grown as single plants. Four per cent of the seedlings have white flowers.

The relation of ear characters of corn to yield, C. C. Cunningham (Jour. Amer. Soc. Agron., 8 (1916), No. 3, pp. 188-196).—This paper is a discussion of some investigations conducted at the Kansas Experiment Station as to the relation of certain ear characters of corn to yield. A brief review of the literature bearing directly on the subject is also given. The data presented were compiled from ear-to-row tests and include the relations to yield of length of ear, circumference of ear, filling out of tips, rounding out of butts, indentation, percentage of grain, and number of rows. The varieties used in the test were Boone County White, Reid Yellow Dent, Hildreth Yellow Dent, Kansas Sunflower, Hogue Yellow Dent, McAuley White Dent, Legal Tender, Leaming, and Pride of Saline.

The data presented indicate that certain ear characters have been overemphasized as to their worth as related to yield, while other characters have been emphasized that may actually tend to decrease yield. Considerably more information is deemed necessary before drawing definite conclusions, especially in regard to those characters whose correlation with yielding capacity may vary with soil and climatic conditions.

Lobed leaves in maize, J. H. Kempton (Jour. Heredity, 7 (1916), No. 11, pp. 508-510, fig. 1).—Early in 1911 an abnormality was observed in a Russian variety of maize and later was found on all of 90 varieties planted that season at Lanham, Md. This abnormality consisted of a pronounced lobing of the

leaves, but the lobes were not mere tears, as was evident from the fact that the margins of the lobes, like those of all normal leaves, were beset with long brittle hairs and a double row of short saw-like teeth directed toward the apex of the leaf. That this abnormality was not a local phenomenon was revealed by observations made by Blaringhem in France and Gernert in Illinois.

The cause of lobing was not fully understood until dissecting some very small lateral branches of Euchlæna, it was noticed that several shoots were prevented from unfurling by having the margins of one of the leaf blades firmly held together with lobes. By examining smaller shoots the stage was finally reached where the lobes were just being formed. It was at once evident that the lobes were formed by the margins of the leaf blades cutting each other where they crossed in unfurling.

"The forcing of the inside margin of the leaf against the outside margin results in the inside margin being cut, but at the same time the outside margin also receives a slight cut through which the lobe on the inside margin grows. As this lobe grows it cuts up into the outside margin, which accounts for the small back cut sometimes found on one margin of the more perfect specimens."

The slight rupture of the tissue, which is extremely tender, results in the separated cells developing independently of the remainder of the leaf blade. "The fact that the two margins of the same leaf mutually rupture each other accounts for the lobes being most often found in pairs one on each side of the leaf."

Report on corn pollination, IV, M. L. FISHER (*Proc. Ind. Acad. Sci., 1914, pp. 207, 208*).—This is the fourth and last report on some studies of cross pollinating corn (E. S. R., 30, p. 635), and deals with a cross of sweet (male) and Reid Yellow Dent (female).

"In the third year two types of sweet corn were distinguishable, one a large ear with whitish kernels and white cobs like the original Stowell Evergreen, and the other a smaller ear with yellowish kernels and red cobs." The quality of the corn when cooked was excellent, the yellow-kernel, red-cob type being slightly sweeter and also earlier maturing

In the season of 1913 three plantings were made, two of the white-kernel, white-cob type in local gardens and the third of both types in the trial gardens of a commercial seedsman at Detroit, Mich. The Detroit tests were reported on as follows:

"The salient features of our reports are to the effect that neither of your selections seem as yet well enough fixed in type to be ready for presentation. Both show a large percentage of reversion to plain parent stock. They are both late and half of the ears in our trial were irregularly and poorly filled. Quality seems excellent, but the color of the red cob shows badly in cooking. From a seedsman's standpoint we do not believe the strains to be as yet of any value."

Sufficient seed is still on hand for further trials and it is hoped that a successful and fixed variety may yet be established.

Delbridge cotton seed calculator, C. L. Delbridge (St. Louis: The Delbridge Co., 1916, pp. 129).—This is a table for calculating the value of any amount of cotton seed within the limits of \$30.25 and \$60 per ton.

Methi as a fodder crop in the Nasik District, M. G. ATHALYE (*Poona Agr. Col. Mag.*, 7 (1916) No. 4, pp. 226, 227).—Brief notes are given on the production of methi as a green fodder crop in India. This crop is frequently used to prepare ground for sugar cane or onions, and is usually grown under well irrigation.

Disadvantage of continuous oat culture on a highly nitrogenous moor soil, H. von Feilitzen (Svenska Mosskulturför. Tidskr., 30 (1916), No. 3, pp. 269-273, fig. 1).—The results of experiments here described indicated that on good

moor soil with sufficient nitrogen oats grown in rotation will give much higher yields than when grown continuously, provided any lacking plant food is supplied. Under continuous culture it was found that the land could not be kept free from weeds, which hindered the development of the crop. It is recommended that land in a very weedy condition should be kept in bare fallow for a year before crop culture is attempted.

Arachis hypogæa, G. C. Dudgeon (Min. Agr. Egypt, Agr. Prod. No. 2a (1916), pp. 24, pl. 1).—This is a detailed discussion of the production and uses of the peanut in Egypt. A botanical description of the more common varieties is given, together with a comprehensive review of the history of the crop. Preparation of the seed bed, cultivation, and harvesting are discussed in turn for both upper and lower Egypt.

Statistics are given on the yield of nuts and fodder.

Potato fertilizers, T. C. Johnson (Virginia Truck Sta. Bul. 21 (1916), pp. 429-452, figs. 4).—Truck crop potato fertilizer experiments conducted at the Virginia Truck Station and the Tasley (Accomac County) substation are reported. The plan of the experiments included the application of commercial fertilizers at the rate of 1,600 lbs. per acre, containing varying proportions of nitrogen, phosphoric acid, and potash. To determine the relative effects of the fertilizer on early, midseason, and late production one-third of each plat at Norfolk was harvested June 14, shortly after the blossoms had fallen, the second third June 22, and the last third July 3, at which time the vines were practically mature. The first harvest at Tasley was June 27-28, the second July 7, and the third July 17. Tabulated data show the yields of each plat for each harvest, together with the percentage increase or decrease.

The largest acre yields were obtained with a mixture containing the equivalent of 5 per cent of ammonia, 6 per cent of phosphoric acid, and 5 per cent of potash at both Norfolk (first and second harvests) and Tasley. A mixture equivalent to 9 per cent of ammonia, 6 per cent of phosphoric acid, and 5 per cent of potash resulted in the highest yield for the third harvest at Norfolk. Excellent results at both Norfolk and Tasley, based on percentage increase, were obtained with a 7:8:5 mixture.

The tests indicate that where the soil has received heavy applications of organic matter a fertilizer containing an equivalent of 5 per cent of ammonia should be satisfactory, but that a soil deficient in organic matter would give better results with one containing 7 per cent. At least 8 per cent of phosphoric acid should be used, better results being secured with this amount in all cases than with smaller quantities. Mixtures containing 3 and 5 per cent potash showed very satisfactory results, while those containing 7 and 10 per cent were not satisfactory at the first and second harvests, the excess of potash evidently delaying maturity.

The effect of removing the tops on the bearing of potatoes, O. SCHLUM-BERGER (Mitt. K. Biol. Anst. Land u. Forstw., No. 15 (1914), pp. 11-13).—In case of potatoes planted April 15 and deprived of their tops at different dates, it was found that the number of tubers produced was slightly lowered by removal of the tops July 21, and much more by their removal June 20. The total weight of the tubers was considerably reduced in both cases, particularly the latter.

[Potato varieties] (Agr. Gaz. Canada, 3 (1916), No. 4, p. 372).—Potato varieties found to be best adapted at each of 11 experimental centers in Canada are listed. Prominent among the early varieties are Early Ohio, Early Rose, and Irish Cobbler, and among the medium or late varieties, Carman No. 1 and Green Mountain.

Potatoes in California, J. W. Gilmore (California Sta. Circ. 161 (1917), pp. 8).—This is a general discussion of potato production in California, including cultural directions. The average cost of the preparation of the land and the growing of the crop, exclusive of harvesting, is estimated at approximately \$28.75 per acre.

139

Potato growing in Washington, I, O. M. Morris (Washington Sta. Popular Bul. 106 (1917), pp. 3-14).—This is a brief general discussion of potato growing under Washington conditions.

Branching-headed rye grass, A. W. Green (Jour. Agr. [New Zeal.], 12 (1916), No. 2, pp. 122-124, fig. 1).—Some brief notes are given on branching in the heads of rye grass. The author states that seldom more than 10 per cent of the progeny of branched individuals possessed similar characters. The plants possessing branched heads were more vigorous than normal plants.

The botanical description of some varieties of Java and other canes, G. L. FAWCETT (Rev. Indus. y Agr. Tucuman, 6 (1916), No. 12, pp. 509-523, figs. 3).—Several varieties of sugar cane are described, and a key devised for their identification.

Varieties of sugar cane.—The result of five years' experiments, A. H. Rosenfeld (Rev. Indus. y Agr. Tucuman, 6 (1915), No. 6, pp. 231-278).—This is an extended report of five years of variety testing of sugar cane in Tucuman. A large number of varieties were compared as regards the comparative yielding ability of native and foreign varieties, the highest sugar-producing varieties, the varieties most resistant to insects and diseases, the varieties best adapted to temperature changes, and the varieties which furnish more and better fuel.

Two Java varieties, designated as Java 36 and Java 213, and Barbados 3277 are recommended most highly as the result of these trials.

The planting of sugar cane in single and double rows, W. E. Cross (Rev. Indus. y Agr. Tucuman, 7 (1916), No. 4, pp. 127-132).—Some notes are given on tests begun by A. H. Rosenfeld on the planting of sugar cane in single and double rows. The results obtained indicate consistently higher yields where the cane was planted in double rows.

A comparison of planting thin canes with canes of ordinary size, W. E. Cross (Rev. Indus. y Agr. Tucuman, 7 (1916), No. 4, pp. 160, 161).—Brief notes are given on experiments begun by A. H. Rosenfeld to compare the planting of sugar cane in the usual manner with the planting of thin canes.

The results obtained indicate that the use of thin canes slightly increased the yield. An average of 28,619 kg. per hectare (12.7 tons per acre) was obtained from the common method and 29,267 kg. from planting thin canes.

Trials with thinning sugar cane in the row, W. E. Cross (*Rev. Indus. y Agr. Tucuman*, 7 (1916), No. 4, pp. 145, 146).—This reports the continuation of work begun in 1911 by A. H. Rosenfeld and J. A. Hall, and previously noted (E. S. R., 31, p. 42). After five consecutive years the results show that the average yield for the five-year period without thinning has been 35,440 kg. per hectare (15.8 tons per acre), as compared with 31,967 kg. when the cane was thinned.

Suggestions relative to the cultivation of sugar cane in Tucuman, J. H. Wale (Rev. Indus. y Agr. Tucuman, 6 (1915), No. 5, pp. 185-188).—This is a general discussion of the cultivation of sugar cane in Tucuman, with special reference to planting.

A study of the adsali cane, R. G. Padhye (Poona Agr. Col. Mag., 7 (1915), No. 1, pp. 60-66, pl. 1).—Some notes are given on the production of "adsali" cane, or "18-months" cane, in India. This practice is followed to delay the harvesting of the cane until after the monsoon period. Analyses of the juice show

that the purity of adsali cane, if standing, is higher than 90 per cent, and if lodged, from 80 to 85 per cent. Although the cane deteriorates in hot weather, a regular increase in the purity of the juice takes place as the monsoon sets in, especially in the lower and middle portions of the cane.

Japanese sugar cane as a forage crop, A. H. Leidigh, G. T. McNess, and H. H. Laude (*Texas Sta. Bul. 195 (1916)*, pp. 3-28, figs. 7).—The adaptation of Japanese sugar cane to the Gulf coast region of Texas and its production and use as a forage crop are discussed.

Observations of the crop under adverse weather conditions indicate that it possesses remarkable yielding qualities under such conditions; that it can grow on damp, undrained soils and resist floods better than any of the crops commonly grown in that region; and that it is decidedly resistant to frost. As a forage crop it is reported as producing a succulent feed at less cost in that region than sorghum or corn silage and comparing favorably with these crops in the feeding value of its green fodder. Comparative analyses indicate that the cane is lower in protein content than green sorghum or sorghum hay, Johnson grass, or Sudan grass hay, but its high sugar content, cheapness, and succulence make it valuable as the basis of a ration balanced by the use of cottonseed meal, peanut hay, or some other nitrogenous feed.

Depth-of-plowing and rate-of-seeding tests indicate that the highest yields are obtained from plowing to a depth of from 12 to 14 in., and that thick plantings (3,000 to 4,000 lbs. of seed canes per acre) are preferable. Although the yield of forage probably decreases considerably after the first season, with proper care the crop may be grown several years without replanting.

Sweet clover, F. M. Lutts (Mo. Bul. Ohio Sta., 2 (1917), No. 2, pp. 45-47, fig. 1).—This briefly notes a test with sweet clover, at the Paulding County experiment farm, in comparison with red clover and mammoth clover as a crop to follow oats and be plowed under in the fall for the succeeding corn crop. The superior root development of sweet clover, especially in time of drought, is emphasized.

The flowering habits of timothy, M. W. Evans (Jour. Amer. Soc. Agron., 8 (1916), No. 5, pp. 299-309, pl. 1).—This paper gives the results of observations on the flowering habits of timothy, made during the blooming period in 1912, 1913, 1914, and 1915, at the Timothy-Breeding Station, New London, Ohio, which is conducted cooperatively by the United States Department of Agriculture and the Ohio Experiment Station. Special attention was given to the time of blooming, length of the blooming period, how and at what time of day the flowers open, the conditions under which they open most readily, the color of various parts of the flower and the general color effect of meadows, and other phases of the blooming process. The observations may be briefly summarized as follows:

When timothy blooms the anthers emerge first and then the stigmas. Anthers do not dehisce until the stigmas of the same flower have been exposed for some time. The flowers on the upper portion of the spike bloom first, with those lower down coming into bloom on succeeding days. The flowers on a single spike may bloom from 6 to 16 days. The period of bloom in northern Ohio extends from June 16 or 20 to July 12 or 15, although the bulk of the blooming is from June 24 or 26 to July 3 or 5. The greatest number of flowers bloom from midnight until sunrise.

The number of flowers that bloom each day, as well as the time of blooming, are affected by climatic conditions, especially temperature. Clear weather and a minimum temperature of 60° F. are most favorable. Timothy was not observed blooming when the temperature during the preceding 24 hours was as

low as 50°. Timothy cut during the blooming period will bloom 12 hours or more after cutting, providing that the hay has not wilted.

The color of timothy bloom varies greatly, due chiefly to the changes in the color of the anther and the anther sack and the variations in the number of flowers that bloom on different days. When weather conditions are favorable, timothy blooming may be regarded as a continuous process to the end of the blooming period, and the so-called "first" and "second" bloom, or the "blue" and "gray" bloom, are misnomers.

On the improvement of Red Olona, P. VENINO (Ann. Ist. Agr. [Milan], 12 (1913-14), pp. 109, 110).—This is a brief note on the improvement of Red Olona wheat through selection since 1910.

The roots of zacaton and their exploitation, I. R. MARTINEZ (La Raiz de Zacaton y su Exploitacion. Mexico: Govt., 1914, pp. 26 pls. 12).—Three varieties of zacaton are described and illustrated, namely, Festuca amplissima, Muchlembergia gracilis, and Epicampes stricta. The fiber is extracted by means of a macerating machine, bleached with sulphurous acid, and classified according to length and color. Directions and regulations are given regarding the exploiting of the product.

Correlation phenomena in the physical properties of grain and their practical significance, M. AKEMINE (Jour. Col. Agr. Tohoku Imp. Univ., 7 (1916), No. 2, pp. 101-127).—This article is a discussion of some investigations dealing with the correlations existing between certain of the physical properties of the seed of rice, barley, wheat, and naked barley as to absolute weight and (1) length, breadth, or thickness, (2) volume, (3) size of the embryo, and (4) specific gravity. The author summarizes his conclusions as follows:

In whole ripe seed the correlation between absolute weight and length or breadth is significant. In the same seeds a correlation between the absolute weight and thickness is very slight, but in unripe seed such a correlation exists. In whole ripe seed the correlation between absolute weight and the volume is very significant. In the same seed a significant correlation exists between absolute weight and the size of the embryo except in hulled rice, in which case the correlation is negligible—for what reason is not yet clear.

There is no correlation between absolute weight and specific gravity, and a sorting method based on specific gravity can only be applied to the separating of ripe, whole or dry seed from unripe, broken or wet seed. Seed sorting based on the absolute weight by means of air currents is a theoretical certainty, but further improvement must be made in regulating the strength of the air current.

A brief bibliography is given at the end of the article.

The possibility of combating plant diseases by means of careful seed selection, E. Henning (K. Landtbr. Akad. Handl. och Tidskr., 55 (1916), No. 4, pp. 282-300, fig. 1).—This is a paper presented before the Royal Agricultural Academy of Sweden reviewing the history of seed control work, together with the results of the more important investigations conducted from time to time to increase the accuracy and reliability of seed testing. It is also pointed out how various factors, especially the influences of plant diseases, may affect the results of seed growth by reducing the viability below that indicated by the seed examination.

Twelfth annual report of the Canadian Seed Growers' Association for the year ending March 31, 1916 (Canad. Seed Growers' Assoc. Ann. Rpt., 12 (1916), pp. 32).—A list of the operating members is given which includes the kind and variety of crops grown and the number of years the seed is known to have been selected.

Conversion of fern-land into grass, A. H. Cockayne (Jour. Agr. [New Zeal.], 12 (1916), No. 6, pp. 421-439, figs. 9).—This article discusses in some detail the suppression of the fern as a weed in New Zealand by the seeding of fern land to pasture grasses. The following grass mixture is recommended: Cocksfoot 8 lbs., Danthonia pilosa 5 lbs., Poa pratensis 3 lbs., Chewings fescue 5 lbs., crested dogstail 2 lbs., P. nemoralis 2 lbs., white clover 1 lb., and Lotus angustissimus 0.5 lb., a total of 26.5 lbs., to which should be added a few pounds of Italian rye grass for quick results.

Goat's rue (Galega officinalis), A. H. COCKAYNE (Jour. Agr. [New Zeal.], 12 (1916), No. 2, pp. 125-130, fig. 1).—This is a botanical and popular description of goat's rue (G. officinalis), which has lately been added to the schedule of "noxious" plants under the Noxious Weeds Act of New Zealand. Notes are given on its cultural habits and methods of control.

[Field crops], M. HOFFMANN ET AL. (Jahresber. Landw., 29 (1914), pp. 72-179).—German literature on the subject of field crops is classified and reviewed in the usual manner.

#### HORTICULTURE.

Report of the horticultural division, J. E. Higgins (*Hawaii Sta. Rpt. 1916*, pp. 13-21, pls. 2).—The horticultural work was continued largely along lines previously noted (E. S. R., 35, p. 538).

With the view of securing improved commercial varieties of pineapples for Hawaii preliminary work in breeding and selection, both among cultivated varieties and seedling forms, was started. The station is collecting varieties grown in different parts of the world, and a number of local seedlings are also being grown. Satisfactory methods, here described, have been devised for the germination of pineapple seeds and the growing of the young seedlings beyond the critical period.

The cooperative experiments with the litchi were continued. Over 1,000 seeds were successfully shipped from Hawaii to Florida in slightly moist sphagnum moss, wrapped in waxed paper surrounded by corrugated strawboard. The water added to the moss equaled half the weight of the dry moss. A disease of litchi leaves similar to the erinose disease of the grape and which has been named litchi erinose was under observation and treatment. The injury is caused by an undescribed Eriophyes species of mite and can be controlled by spraying the trees several times with nicotin sulphate and whale-oil soap mixed at the rate of 10 oz. of nicotin sulphate and 1.75 lbs. of whale-oil soap to 50 gal. of water. The treatment is more effective if the seriously damaged leaves are removed before spraying. The longan tree, a related species, was not infested with this mite although surrounded by infested litchi trees.

In the breeding work with avocados and mangos a number of apparent crosses were secured during the season. The technique thus far developed in cross-pollinating mangos is described. Breeding work with papayas was continued with the view of securing a pure elongata strain as well as further data on the determination of sex and the combining of desired characters. Seventy-two supposed seedling crosses of the Chinese wood oil nut (Aleurites fordii) and the Hawaiian kukui nut (A. moluccana) are under observation.

Notes are given on the condition of the station orchards and miscellaneous plantings at the Tantalus substation.

[New fruit trees, ornamentals, and other plants], N. E. HANSEN (South Dakota Sta. Rpt. 1916, pp. 22-26).—This comprises brief descriptions of some new trees and plants sent out by the station for trial in the spring of 1916. The list includes the Ivan and Dolgo crab apples; Sereda, Adno, and Hibkee

apples; some seedling plums; a Turkestan radish and Siberian muskmelons and watermelons found by the author; Siberian forms of almond, buckthorn, and Layatera; Rosa rugosa; Manitoba hazelnut; and New Ulm black walnut.

Attention is called to the value of Siberian and Hybrid Siberian crab apples as important stocks for insuring freedom from root killing. In the station orchard the Wealthy apple has borne abundantly on the Siberian stock.

Notes on novelties and plants not well known, F. E. Buck (Ann. Rpt. Hort. Socs. Ont., 11 (1916), pp. 95, 96).—Brief descriptive notes are given on flowers and plants grown in the test plats of the Central Experimental Farm for the first time during the season of 1916.

Calendar for the treatment of plant diseases and insect pests, W. J. GREEN, A. D. Selby, and H. A. Gossard (Ohio Sta. Bul. 309 (1917), pp. 485-516, figs. 3).—A revised edition of Bulletin 232, previously noted (E. S. R., 26, p. 539).

Winter sprays: Lime-sulphur spray and crude oil emulsions, A. L. MELANDER (Washington Sta. Popular Bul. 107 (1917), pp. 12).—A revised edition of Popular Bulletin 64 of the station, previously noted (E. S. R., 31, p. 740).

Cabbage and cauliflower culture, C. B. Sprague (Washington Sta. Popular Bul. 110 (1917), pp. 4).—A popular treatise on the climatic and soil requirements, culture, harvesting, and storage of cabbage and cauliflower.

Celery culture, F. W. Allen (Washington Sta. Popular Bul. 109 (1917), pp. 4).—A treatise similar to the above.

Lettuce growing in California, S. S. Rogers (California Sta. Circ. 160 (1917), pp. 16, figs. 11).—This circular discusses the classification of lettuce, importance of the industry in California, lettuce growing districts in California, cost of production, yields, profits, cultural requirements, harvesting, packing, varieties, and crop troubles.

Growing tomatoes on stakes: Advantages, increased profits, and proper methods of culture, S. N. Green (Mo. Bul. Ohio Sta., 2 (1917), No. 3, pp. 91-95, figs. 2).—This paper presents some data based on information secured from practical growers, as well as on tests conducted by the station, showing the proper methods of growing tomatoes on stakes, together with the advantages and increased profits therefrom.

Forms of some Philippine fruits, J. de Leon Y German (*Philippine Agr. and Forester*, 5 (1916), No. 8, pp. 251-283, figs. 16).—In the present study the author aims to show the importance of improving varieties of fruits by the selection of the best native forms and propagating them vegetatively. Various native varieties of fruits are here described.

Irrigation of orchards, F. Adams (Cal. Citrogr., 2 (1917), No. 7, pp. 2, 3, figs. 2).—A paper on this subject read at the Citrus Institute, Riverside, Cal.

The Maryland apple grading and packing law, T. B. Symons and S. B. Shaw (Md. Agr. Ext. Serv. Bul. 1 (1916), pp. 23, figs. 10).—This bulletin gives the text of the Maryland apple grading and packing law, calls attention to similar laws enacted by other States and by the Federal Government, explains the requirements of the law, and gives suggestions relative to harvesting, grading, and packing apples.

Cooperative organization, G. V. Branch (Ann. Rpt. State Hort. Maine, 5 (1915) pp. 35-43).—An address to the apple growers of Maine in which the author points out the benefits of cooperative organization in marketing.

North American varieties of the strawberry, S. W. Fletcher (Virginia Sta. Tech. Bul. 11 (1916), pp. 3-126, figs. 19).—This bulletin, which comprises a descriptive list of 1,879 varieties of strawberries, includes all varieties that have originated in North America so far as can be discovered from an extensive review of the literature of the subject. A bibliography of North America

can literature on the strawberry, exclusive of articles on injurious insects and diseases, is also given.

Some viticultural and enological experiments conducted at the Paarl Viticultural Experiment Station during 1915-16, A. I. PEROLD (Union So. Africa Dept. Agr. [Pub.], 21 (1916), pp. 13).—This briefly summarizes the results of pruning, training, thinning, and other experiments with table grapes, as well as some experiments in wine making, conducted at the Paarl Viticultural Experiment Station during 1915-16.

California's grape industry (Cal. Bd. Vit. Comrs. Bul. 8 (1917), pp. 24).—A statistical review of the grape industry of California for the year 1916. During the year a total of 10,741 cars of grapes were shipped to points outside of the State. The estimated raisin production for the year was 126,000 tons. About 478,197 tons of grapes were used in the production of wine and brandy.

The culture of the olive (Olea europaea) on the southern shore of the Crimea, E. V. Wolf, F. K. Kalaïda, and G. A. Plotnitskii (Bot. Kab. i Bot. Sad Imp. Nikitsk. Sada [Pub.] No. 1 (1916), pp. 24, flgs. 9).—Some results are given of experimental tests in propagating and planting olives and the extraction of oil from various species.

Maintenance of fertility of pineapple fields, F. G. Krauss (Hawaii Sta. Rpt. 1916, pp. 36-38).—An account is given of cooperative demonstration experiments being conducted on the plantation of the Haiku Fruit and Packing Company for the purpose of testing the accumulative renovating power of green-manuring legumes.

Station work for the avocado, H. J. Webber (Rpt. Cal. Avocado Assoc., 1915, pp. 69-72).—This paper comprises a brief statement of investigations with avocados being conducted under the direction of the Citrus Experiment Station.

Varieties of the avocado, F. O. POPENOE (Rpt. Cal. Avocado Assoc., 1915, pp. 44-69).—Previously noted from another source (E. S. R., 35, p. 448).

The avocado in Florida and other lands, W. POPENOE (Rpt. Cal. Avocado Assoc., 1915, pp. 29-42).—In this paper the author gives a general account of avocado culture and the importance of the industry in Florida and the West Indies.

Citrus fruit improvement: How to secure and use tree performance records, A. D. SHAMEL (U. S. Dept. Agr., Farmers' Bul. 794 (1917), pp. 16, figs. 4).— This publication is based upon the results obtained in bud selection experiments in California citrus groves which have been under way since 1909 (E. S. R., 36, pp. 141, 537). It describes the methods that have been found effective and practical in locating the desirable and undesirable trees in groves and for transforming the latter when found.

Records and accounts for citrus groves, R. S. Valle (Cal. Citrogr., 2 (1917). No. 7, pp. 7, 8, figs. 2).—A discussion of cost accounting with special reference to citrus groves in southern California.

[Coconuts, rubber, coffee, and cacao], J. B. HARRISON (Rpt. Dept. Sci. and Agr. Brit. Guiana, 1914-15, pp. 15-21).—A brief statistical review of the abovenamed crops, including the progress made in cultural experiments at the Georgetown Botanic Gardens and at the Onderneeming Farm.

Experiments in manuring of cacao, M. K. Bamber and D. S. Coblett (Dept. Agr. Ceylon Bul. 26 (1916), pp. 9).—The results are given of manurial experiments with cacao in which the trees were continuously manured during the period from 1902 to 1911, inclusive, but since which period manures have been withheld.

The principal feature of the experiment was the permanent beneficial effect of castor pomace, which, during the 10-year manurial period, had been applied annually at the rate of 833 lbs. per acre, containing 50 lbs. of nitrogen. This

plat gave poor results for some years during the application, but later it steadily increased from the twelfth to the first place, which it has held for the last two years it received no manure. A new series of manurial experiments started in 1915 is here outlined.

Culture of the pistachio tree (Pistacia vera) on the southern shore of the Crimea, F. K. Kalaĭda (Bot. Kab. i Bot. Sad Imp. Nikitsk. Sada [Pub.] No. 2 (1916), pp. 22, pls. 8, figs. 2).—Directions are given for propagating and growing the pistachio tree, based upon experience in the Imperial orchard at Nikitsky.

The cultivation and drying of medicinal plants, E. M. Holmes (Sevenoaks, England: Author, 1916, pp. 15).—A lecture on this subject embracing the results of the author's observations and experience for a number of years in the cultivation of medicinal plants.

One hundred flowers, H. HAVERSTICK (Hershey, Penn.: Hershey Press, 1917, pp. 91, ftgs. 16).—In this work the author describes and gives directions for growing 100 decorative flowers and plants, including old-time favorites and the best of the new ones, the subject matter being based upon personal observation and experience.

The book of the peony, Mrs. E. Harding (Philadelphia and London: J. B. Lippincott Co., 1917, pp. 259, pls. 43, figs. 8).—A treatise on the peony, discussing its mythology, ancient and modern history, best varieties and their characteristics, methods of extending the period of bloom, purchasing peonies, where to plant and how to prepare the soil, planting and cultivation, and propagation. Chapters are also devoted to the history, description, cultivation, propagation, and best varieties of tree peonies.

The American rose annual, edited by J. H. McFarland (Harrisburg, Penn.: American Rose Society, 1917, pp. 161, pls. 10, figs. 7).—This annual comprises numerous articles by various authorities on roses dealing with the following subjects: The use of the rose in the landscape, the literature of the rose, the American rose advance, methods of rose growing, rose importations, how to conduct an amateur rose show, the rose all over America, the enemies of the rose, cut-flower rose growing, a partial list of roses introduced in America, and the work of the American Rose Society.

A bud variation of Euonymus, A. D. Shamel (Jour. Heredity, 8 (1917) No. 5, pp. 218-220, figs. 2).—The author calls attention to a variegated form of E. japonicus as an illustration of a valuable cultivated variety produced through the propagation of bud variations, the variegated form being a bud variation of the green form.

Aristocrats of the garden, E. H. WILSON (Garden City, N. Y.: Doubleday, Page & Co., 1917, pp. VII+312, pls. 16).—This work comprises a series of articles on ornamental plants previously noted (E. S. R., 35, pp. 345, 450).

Garden guide.—The amateur gardener's handbook, edited by J. H. Dick (New York: A. T. De La Mare Co., 1917, pp. 255, figs. 173).—A compilation of information relative to planning, planting, and maintaining the home grounds, the suburban garden, and the city lot, including lists of plants for various purposes, together with chapters on garden furniture and accessories.

Back yard gardening for business men, T. R. Best (New York: Street & Smith, 1917, pp. 125, figs. 2).—A popular treatise discussing opportunities in the back yard and giving directions for growing the more important vegetables.

Street and park trees for Wisconsin communities, M. A. CASTLE (Wis. Conserv. Com. Bul. 2 (1916), pp. 54, ftys. 32).—A compilation of material dealing with the planting and care of street and park trees, including lists of trees and shrubs for planting in different situations.

Turf for golf courses, C. V. Piper and R. A. Oakley (New York: The Macmillan Co., 1917, pp. XVII+262, pls. 20, figs. 50).—A treatise on growing turf for golf courses, the successive chapters of which discuss soils for turf grasses; fertilizers; manures, composts, and other humus materials; lime and its use; the important turf plants; how to distinguish different kinds of turf; the turf grasses for different purposes; the making of the turf; subsequent care; weeds and their control; animal pests; turf machinery; experimental work on golf courses; and personal experiences.

## FORESTRY.

Report of the superintendent of forestry, C. S. Judd ([Bien.] Rpt. Bd. Comrs. Agr. and Forestry Hawaii, 1915-16, pp. 23-48, pls. 8).—A report for the calendar years 1915 and 1916 relative to the work of forest protection, operations on the Government reserves and nurseries, private planting work, and miscellaneous activities.

During the past biennial period two more forest reserves have been added to the general forest-reserve system, making a total of 39, with a total area of 798,344 acres, of which 546,352 acres is Government land.

Report of the forest nurseryman, D. Haughs ([Bicn.] Rpt. Bd. Comrs. Agr. and Forestry Hawaii, 1915-16, pp. 54-59).—A report for the years 1915 and 1916 relative to collection and exchange of seed, trees distributed from the Government nurseries, and miscellaneous work.

Annual administration report of the forest department of the Madras Presidency for the twelve months ended June 30, 1916, F. L. C. Cowley-Brown, H. B. Bryant, P. M. Lushington, H. A. Latham, et al. (Ann. Admin. Rpt. Forest Dept. Madras, 1916, pp. 73+LIX+16).—The usual progress report relative to the administration of the State forests in the Northern, Central, Southern, and Western Circles of the Madras Presidency, including a financial statement for the year ended June 30, 1916. All important data relative to alterations in forest areas, working plans, surveys, miscellaneous work, yields in major and minor forest products, revenues, expenditures, etc., are appended in tabular form.

Annual progress report on forest administration in the Province of Bihar and Orissa for the year 1915-16, H. H. Haines (Ann. Rpt. Forest Admin. Bihar and Orissa, 1915-16, pp. 11+56+4).—A report similar to the above relative to the administration of the State forests of the Province of Bihar and Orissa.

Annual report on the forest administration in Ajmer-Merwara for the year 1915-16, Hukam Chand (Ann. Rpt. Forest Admin. Ajmer-Merwara, 1915-16, pp. 3+29).—A report similar to the above relative to the administration of the State forests of Ajmer-Merwara.

Progress report of forest administration in the Province of Assam for the year 1915-16, W. F. L. TOTTENHAM and A. W. BLUNT (Rpt. Forest Admin. Assam, 1915-16 pp. 2+24+55+3, pl. 1).—A report similar to the above relative to the administration of the State forests of Assam.

Progress report of forest administration in the Punjab for the year 1915-16, R. McIntosh (Rpt. Forest Admin. Punjab, 1915-16, pp. [12]+14+LXVII, pl. 1).—A report similar to the above relative to the administration of the State forests of the Punjab.

Tree planting in eastern Washington, O. M. Morris (Washington Sta. Popular Bul. 108 (1917), pp. 4).—Practical directions are given for planting trees, including a descriptive list of varieties recommended for eastern Washington.

Ornamental windbreaks.—Evergreens are grouped with small trees and flowering shrubs, W. E. Bontrager (Mo. Bul. Ohio Sta., 2 (1917), No. 3, pp. 82-84, fig. 1).—This paper presents suggestions relative to the use of ornamental trees in the development of windbreaks for protecting orchards, gardens, barnyards, etc.

Investigation on the optimum limit of intensity of thinnings, E. Mer (Rev. Eaux et Forêts, 55 (1917), Nos. 2, pp. 33-43; 3, pp. 65-72).—In continuation of previous papers (E. S. R., 36, p. 345) the author gives the results secured from thinnings of different intensities in some selected fir stands that were thinned in 1886 and in 1899.

Toxic atrophy, E. A. Woodbuffe-Peacock (Quart. Jour. Forestry, 11 (1917), No. 2, pp. 88-93).—In this paper the author presents his views relative to toxic atrophy as an important factor in the failure of species to reproduce themselves in woodlands.

The forests of Quebec, A. Bedard (Statis. Year Book Prov. Quebec, 1916, pp. 414-428).—A short description of the three forest zones in Quebec, including some statistical and economic considerations.

Notes on some North American conifers based on leaf characters, L. W. Durrell (Proc. Iowa Acad. Sci., 23 (1916), pp. 519-582, figs. 117).—The author here presents a series of drawings, with descriptive text, of the leaf characters of the arboreal conifers of North America bearing needle leaves, except Pinus. The characters of the same species were found to be constant even though the specimens came from widely separated localities.

The tulip poplar (Liriodendron tulipifera).—A forest tree of important commercial value for Ohio, A. E. Taylor (Mo. Bul. Ohio Sta., 2 (1917), No. 2, pp. 51-58, figs. 4).—An account of the tulip poplar with reference to its characteristics, soil and light requirements, commercial value, and silvical management.

On the mode of occurrence of latex vessels in Hevea brasiliensis, G. BRYCE and L. E. CAMPBELL (Dept. Agr. Ceylon Bul. 30 (1917), pp. 22).—The authors here record a study of the distribution and mode of occurrence of latex vessels as observed in a number of untapped trees at the Peradeniya Experiment Station, as well as in trees growing on plantations in several different districts of Ceylon.

Tapping experiments at Gunong Angsi, F. G. Spring and B. Bunting (Agr. Bul. Fed. Malay States, 5 (1917), No. 4, pp. 111-123).—In continuation of previous work (E. S. R., 30, p. 535) the results of the third season are given on tapping experiments with rubber to determine the relative yields from adjacent and opposite quarters with both daily and alternate tapping.

The results thus far secured indicate that the yield from adjacent quarters of the tree (double V cuts) is approximately 18 per cent greater than that from opposite quarters of the tree. The daily tapping of adjacent quarters gave 26 per cent more rubber than opposite quarters, while on alternate-day tapping the difference in favor of adjacent quarters was only 9.5 per cent. Opposite quarters not only gave much poorer total yields and higher percentages of scrap rubber than adjacent quarters but had the disadvantage of having two distinct tapping areas which makes the system much more difficult both as regards tapping and supervision.

"Tarwad" bark as a tanning agent, D. B. Limaye (Ranade Indus. and Econ. Inst., Poona, Bul. 1 (1916), pp. 18).—An account of the "tarwad" bark, the product of the perennial shrub Cassia auriculata, with reference to its use for tanning purposes in India. Analysis of tannin content and methods of collecting the bark are also given.

Production of lumber, lath, and shingles in 1915 and lumber in 1914, J. C. Nellis (U. S. Dept. Agr. Bul. 506 (1917), pp. 45, pls. 2, figs. 4).—This bulletin gives detailed statistics on the production of lumber, lath, and shingles in 1915 with comparisons for previous years. The data given include production, by classes of mills, by States, and by kinds of wood. Reports from 16,815 mills showed an aggregate timber cut for 1915 of 31,241,735,000 ft. b. m., from which it is estimated that the total lumber cut of the country was approximately 38,000,000,000,000 ft. b. m.

Forest industries (Statis. Year Book Prov. Quebec, 1916, pp. 429-448).—A statistical survey of the forest products of Quebec for 1915, including comparative data for 1914. An article on the manufacture of wood pulp, by G. C. Piché, is also included.

## DISEASES OF PLANTS.

Additional notes on Philippine plant diseases, C. F. BAKER (Philippine Agr. and Forester, 5 (1916), No. 3, pp. 73-78).—Since the publication of the review of plant diseases previously noted (E. S. R., 32, p. 749), considerable work has been done in this direction by the author and, in collaboration with him, by Rehm, Sydow, Saccardo, and Diedicke, in the determination of parasitic fungi. A number of these are considered as new to science and are named herein, without technical descriptions, in connection with the host plants. These forms include the new varieties Phomopsis palmicola arecæ on Areca catechu and Mycogone cervina theobroma and Nectria bainii hypoleuca on Theobroma cacao; the new species Phyllosticta insularum on Annona muricata, Exosporium pulchellum and Anthostomella arecæ on Areca catechu, Phomotospora migrans on Arenga saccharifera, Diatrypella barleriæ on Barleria cristata, Physalospora guignardioides on Canavalia gladiata, Zignoella nobilis on Citrus nobilis, Exosporium durum and Chatospharia eximia on Cocos nucifera, Phyllosticta euchlænæ on Euchlæna luxurians, Diplodia crebra on Musa sapientum, Oospora oryzetorum, Phyllosticta glumarum, Ophiobolus oryzinus, Sordaria oryzeti, and Coniosporium oryzinum on Oryza sativa, Pionnotes capillacea on Persea gratissima, Pezizella ombrophilacea and Aschersonia parænsis on Psidium guajava, Diplodina degenerans on Solanum melongena, Physalospora affinis and Botryosphæria minuscula on Theobroma cacao, Macrophoma trichosanthis on Trichosanthes anguina, Vermicularia xanthosomatis on Xanthosoma sagittifolium, and Helminthosporium curvulum, Clasterosporium maydicum, Broomella zea, and Acerbia maydis on Zea mays; and the new genera and species Bakerophoma sacchari on Saccharum officinarum and Discothecium bakeri on Trichosanthes anguina.

Some Phycomycetous diseases of cultivated plants in the Philippines, N. Mendiola and R. B. Espino (Philippine Agr. and Forester, 5 (1916), No. 3, pp. 65-72, figs. 2).—It has been found that Phytophthora faberi (P. theobromæ) is the cause of a pod disease of cacao and a fruit disease of papaya, and it is thought that it may develop on other plants in this region. Though the primary agent in the above-mentioned cases, it is quickly followed by other fungi, commonly by Lasiodiplodia.

P. colocasia was found and studied on leaves of gabi (Colocasia antiquorum) at Anos, Los Baños. Pythium debaryanum has been noted in the Philippines as causing a damping-off in seedlings of lettuce, tomato, and other vegetables, also in tobacco plants.

Plant diseases and other injuries, C. BRICK (Hamburg Bot. Staatsinst., Ber. Abt. Pflanzenschutz, 16 (1913-14), pp. 9-21).—This deals with diseases, animal enemies, and other harmful agencies affecting various plants in domestic and

colonial German territory, also in some neighboring countries or foreign lands. The results are briefly indicated of tests with several proprietary or standard fungicidal preparations.

The genus Meliola in Porto Rico, F. L. Stevens (Ill. Biol. Monographs, 2 (1916), No. 4, pp. 473-554, pls. 5).—The author has described material collected in Porto Rico during 1912, 1913, and 1915. This has been arranged in 95 species and 6 varieties of Meliola parasitic on 171 different hosts, 146 of which are said to be new to Porto Rico for Meliola.

Specialization of parasitic fungi, particularly of the cereal rusts, L. Monte-Martini (*Riv. Patol. Veg.*, 8 (1916), *Nos. 2*, pp. 33-44; 6-7, pp. 145-158).—The author, besides giving a bibliographic discussion of this subject, describes a number of his own investigations.

He concludes that parasitic fungi are extremely sensitive to the chemical composition of the nutritive medium on which they live, and under its influence easily acquire characters of adaptation which attain to a certain fixity. In consequence fungi may become unable to flourish on species different from that to which they have accustomed themselves, and even on other portions of the same plant which they inhabit, or in different developmental stages or other conditions of such plant or organ. This unfitness may manifest itself in differences of germinability or of virulence of the spores originating in different situations.

In grain rusts, or at least in *Puccinia rubigo-vera* of rye, which has been made the object of special study by the author, it is stated that these may pass from one to another species of fall or spring wheat and oats, infection varying in an irregular manner even within a single species and a given stage. This matter is further complicated by atmospheric conditions and the influence thereof upon sensitivity to attack as well as upon the infecting bodies. It is thought that temporary adaptation and differences or parallelism of development in both host and parasite may explain what are considered real specializations.

Some septorias of wheat, W. B. Grove (Gard. Chron., 3. ser., 60 (1916), Nos. 1556, p. 194, figs. 3; 1557, p. 210, fig. 1).—The author gives the results of comparing a number of Septorias on wheat sent from west Australia by F. Stoward with some collected in England by J. W. Ellis or by himself.

Practical or complete identity appeared in several cases, some apparent differences arising from such causes as different positions of the fungus on the host plant or age of the different portions attacked. S. nodorum is thus apparently identical with S. glumarum. A specimen causing a dry blight in west Australia is apparently identical with S. graminum in England, though in some respects another specimen approached S. ophioides and may prove to be identical therewith. Other forms or modifications are described, in particular S. graminum crassipes. S. bromi and S. bromi brachypodii are thought to belong to the same species, which is probably widespread, and S. tritici is probably a closely allied form.

Smut of wheat, F. E. Devoto (Min. Agr. Nac. [Buenos Aires], Dir. Gen. Enseñanza e Invest. Agr. [Pub.] No. 53 (1916), pp. 7-12, figs. 5).—This is a discussion of the development, effects, and treatments of the wheat smuts Tilletia tritici and T. lævis, with directions for the preparation of Bordeaux mixture, which appears to be in common use in this region.

Some bacterial diseases of vegetables found in Ontario, D. H. Jones (Ontario Dept. Agr. Bul. 240 (1916), pp. 24, figs. 31).—This bulletin deals with bacterial diseases according to the four general types of change they induce in the host, namely, soft rots, wilts, cankers or blights, and galls.

The cause of bacterial soft rot of various fleshy vegetables, considered as practically one and the same organism, has been discussed under the various

names Bacillus carotovorus, B. oleraceæ, B. melonis, B. aroideæ, and Pseudomonas destructans. Soft rots of potato are associated with B. solanisaprus and a Fusariam, black leg with B. phytophthorus and with a Rhizoctonia. Bacterial wilt of crucifers, also called black rot of cabbage, or brown rot, is associated with P. campestris, and bacterial wilt of cucurbits with B. tracheiphilus. Bean blight, or bacteriosis, is associated with P. phaseoli, which organism appears to be, as regards morphological and cultural characteristics, practically identical with P. campestris. It is not, however, pathogenic for cabbage or cauliflower, while P. campestris is pathogenic for most crucifers but not for legumes.

Club root of crucifers and its control, E. Werth (K. Biol. Anst. Land u. Forstw. Flugbl., 56 (1916), pp. 3, fig. 1).—This circular deals with Plasmodiophora brassica, its persistence in spore form in the soil, its infection of subsequent crops, and its effective control.

Excess of soil water, deficiency of lime, use of one-sided fertilizers, too long a succession of cruciferous crops, and the presence of wild crucifers in fields are among the conditions favoring the perpetuation of the club root organism. Rigid inspection of plantlets, judicious rotation of crops, improvement of physical and chemical conditions in the soil (especially deep plowing with a liberal use of lime), and disinfection of the soil with 5 liters per square meter (4.4 qts. per square yard) of a 2 to 3 per cent solution of formalin are among the measures recommended.

A new host of Ascochyta hortorum, L. Gabotto (Riv. Patol. Veg., 8 (1916), No. 2, pp. 45, 46).—The author records a fungus, supposed to be A. hortorum, as causing an external spotting and an internal rot of artichoke.

Controlling cabbage yellows, S. N. Green and J. G. Humbert (Mo. Bul. Ohio Sta., 2 (1917), No. 2, pp. 37-40, fig. 1).—An account is given of experiments begun in 1911 to develop by careful selection strains of cabbage resistant to the yellows disease caused by Fusarium conglutinans. As a result of these experiments, several resistant strains of a commercial variety of cabbage have been developed.

Potato diseases, F. D. Heald (Washington Sta. Popular Bul. 106 (1917), pp. 15-94, figs. 26).—After a discussion of the loss due to potato diseases, some of their causes, and methods of prevention and control, the author describes nonparasitic diseases, due to unfavorable environment and chemical treatment, and those transmitted by seed, the cause of which is unknown, and parasitic diseases due to bacteria, slime molds, and fungi.

Important potato diseases and their control, R. Schander (Arb. Gesell. Förd. Baues u. Verwend. Kartoffeln, No. 4 (1915), pp. 90, Aps. 19).—This is a synthetic review, chiefly from a practical standpoint, of the principal potato diseases prevalent in Germany, including nematode attack, their effects, and their control.

The osmotic pressure of cell sap in relation to tobacco plants affected with mosaic disease, A. Sprecher (Ann. Jard. Bot. Builenzorg, 2. ser., 14 (1916), pt. 2, pp. 112-128).—The author, describing a series of studies, states that tobacco plants affected with mosaic disease show practically the same freezing point and osmotic pressure as normal plants. The former, however, show lower molecular weights in the substances dissolved in the cell sap, this fact being supposedly connected with a small content in organic, and a large content in mineral, substances.

Tomato fruit diseases, R. Waters (Jour. Agr. [New Zeal.], 12 (1916), No. 3, pp. 198-201, figs. 4).—Notes are given of tomato black rot due to Macrosporium tomato, probably identical with M. solani; circular white patch, supposedly induced by unfavorable weather conditions; and premature softening, which

it is thought may prove to be the incipient stages of the circular white patch condition.

Manual of fruit diseases, L. R. Hesler and H. H. Whetzel (New York: The Macmillan Co., 1917, pp. XX+462, figs. 126).—The authors give popular descriptions, together with suggestions for control, of bacterial and fungus diseases, as well as those of unknown causation, of the apple, apricot, blackberry, cherry, cranberry, currant, gooseberry, grape, peach, pear, plum, quince, raspberry, and strawberry. The various diseases are treated in the order of their usual economic importance. A chapter is devoted to the importance of the preparation of some of the more common copper and sulphur fungicides. The information given is designed for fruit growers and embraces the results of recent investigations.

Bitter pit, D. McAlpine (Fruit World Austral., 17 (1916), No. 1, pp. 2, 3, 5, 7, figs. 2).—The author discusses bitter pit control as regards fruit on the tree, in storage, and in transit, also the influence of resistant stocks.

The trouble is worse on main branches and spurs thereof than on laterals and their spurs, on pruned than on unpruned laterals, on trees bearing a few large fruits than on those bearing many small ones, on trees with large than on those with small bearing surface, on rank than on less profuse growths, and on trees having very abundant or irregular water supply and faulty transpiration. Drainage, cultivation, manuring, and in general maintenance of good conditions are considered important means of prevention and regulation. It has been found that in apples kept at 30 to 32° F. in storage or transit the development of bitter pit and ripening are practically arrested. Breeding of resistant varieties is regarded as a possibility.

The Illinois canker, or the blister canker of the apple tree, D. E. Lewis (Trans. Kans. State Hort. Soc., 33 (1914-15), pp. 175-178).—Observations are summarized on blister canker (Nummularia discreta), said to have been present in Kansas for more than 15 years and very destructive for several years during some of the latter part of that period (owing to the weakening effect of drought). The author outlines the development and the effects of the attack, and the control measures favored, which consist in selection of resistant varieties (some of which are named), and in aeration and general sanitation.

Notes on an apparent relation between aphids and fire blight (Bacillus amylovorus), J. H. Merrill (Trans. Kans. State Hort. Soc., 33 (1914-15), p. 71).—Observations carried on since 1913 in Doniphan County by the department of entomology of the Kansas Experiment Station are said to have shown that where aphids are kept down by spraying with black leaf 40, the percentage of attack by fire blight (B. amylovorus) is greatly diminished and in some cases is practically zero. Comparatively few aphids were found in orchards which had received a thorough dormant spraying with lime-sulphur.

Ripe rot of stone fruits, A. B. Mansfield (Jour. Agr. [New Zeal.], 12 (1916), No. 3, pp. 214-216, figs. 2).—It is stated that in the Auckland districts the loss in stone fruits due to ripe rot (Monilia fructigena) has recently been considerable. The term ripe rot is preferred to that of brown rot, the latter being deemed more appropriate to a similar disease of apples and similar fruits.

Grape downy mildew in Algarve, P. P. M. Judice (Bol. Assoc. Cent. Agr. Portuguesa, 18 (1916), Nos. 3, pp. 81-90; 4, pp. 126-137).—This is an account of observations carried out in the Province of Algarve during a number of years on the intensity of mildew attack in connection with meteorological conditions.

It is stated that the attacks in this region have usually been of comparatively slight intensity, varying from year to year and with the locality in the same year. Some localities never have suffered from mildew attack, so that while three or more treatments are considered as technically advisable, these are not

always justifiable from an economic standpoint. It is stated that in case of much rainfall in spring a preventive treatment applied on the first indications of an outbreak, and followed up as found necessary, is sufficient to control the mildew. In those localities where severe attacks appear annually, with rare exceptions, preventive treatment under competent scientific advice is considered necessary.

Vine mildew in Piedmont, Italy, in 1915, F. Martinotti (Gior. Vin. Ital., 41 (1915), No. 30, pp. 613-615; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 9, p. 1261).—It is stated that downy mildew, while showing variations with the locality and the portion of the plant attacked, caused considerable losses in the vineyards of Piedmont in 1915. This was owing partly to rainy or damp weather and imperfect treatment of the bunches, partly to lack of timeliness in spraying, and partly to the poor quality of the sprays, as shown by analysis of samples of the materials employed.

Treatment of downy mildew, A. Convergne and L. Trouchaud-Verdier (Rev. Vit., 45 (1916), No. 1149, pp. 9-11).—The authors have summarized the principal conclusions arrived at regarding the treatment of downy mildew as instituted in 1915 by the Agricultural Society of Gard.

It is stated that the crop returns were usually to be gauged by the amount of copper in the sprays applied to the vines. Small proprietors obtained relatively good results on account of the timeliness, thoroughness, and frequency of the applications in such cases. Adherence and a sufficiency of copper content proved to be important factors when washing rains were prevalent, 2 per cent of copper being usually sufficient in such a period. Comparable results were given by Bordeaux, Burgundy, and verdigris solutions when properly prepared.

Sprays owe their immediate action to the presence of copper which is immediately soluble, and the efficiency of any spray depends upon its persistence in soluble form on the leaf surface. The question as to how a spray can be prepared that is both immediately effective and durable is not regarded as having been solved. Powders have been used with good effect after spraying, when applied before the surface become dry, but such treatments are regarded as complementary only. The minimum of sprayings required in normal years is about two, one about May 20 and the other about June 10, or just before and just after the flowering period. Circumstances will vary the requirements in this respect as in others.

Treatment of Oïdium, J. Capus (Rev. Vit., 45 (1916), No. 1149, pp. 8, 9).— Experimentation has shown that grapevines when shielded from direct precipitation are largely protected from downy mildew and black rot, but may be severely attacked by Oïdium. Treatment with powdered sulphur, while only preventive in cases of the first two of these diseases, is also in a measure curative in case of Oïdium, and decidedly so when the treatment is employed in clear, warm weather, soon after the outbreak of the disease.

Fog and grape diseases, P. Larue (Rev. Vit., 44 (1916), No. 1145, pp. 411, 412).—Fog is said to increase infection, particularly of grape downy mildew, by favoring the adherence of the infecting bodies to surfaces rendered less resistant or more favorable to their development.

[Treatments for grape troubles], P. Causse (Rev. Vit., 44 (1916), No. 1145, pp. 409-411).—Besides giving a brief discussion of the hot-water treatment for insects, the author states that he considers basic Bordeaux mixture preferable for the treatment of grape downy mildew. Good results have been obtained by treating vines showing court-noue with tar applied to wounds on the stock. The growth was at first backward and the vines looked sickly, but later they attained normal color, growth, and yield.

The effect of asphyxiating gases on grapevines at the battle front, P. Viala (Compt. Rend. Acad. Agr. France, 2 (1916), No. 20, pp. 558-561; Rev. Vit., 44 (1916), No. 1146, pp. 424, 425).—An account is given of the effects upon vegetation, particularly upon grapevines, of exposure to the fumes released by the explosion of aeroplane bombs dropped in raids during the latter part of April, 1916.

Severe injury was caused, which, it was found, could be duplicated by subjecting the vines to chlorin fumes or by sprinkling them with Javelle water. In case of outdoor plants on dry areas, discoloration was not so evident as where dew was present, but the growth was temporarily checked after absorbing the injurious gases. Injury to the other plants varied with the stage of their vegetative advancement. Rye and other cereals were affected.

The effects of asphyxiating gas on vines, A. Cordonnier and Richez-Péchon (*Rev. Vit.*, 44 (1916), No. 1148, pp. 459-461).—This contains a few particulars, in addition to those reported above by Viala, of observations made on forms of injury to plants by fumes from aeroplane bombs.

Effects of gases from aeroplane bombs, A. Cordonnier (Bul. Soc. Path. Veg. France, 3 (1916), No. 1, pp. 32, 33).—This is a brief account of the occurrences and results above noted.

Citrus blast, a new disease in California, J. E. Coit (*Univ. Cal. Jour. Agr.*, 3 (1916), No. 6, pp. 234, 235, figs. 2).—A brief account is given of a new citrus disease which was first observed by the author in the spring of 1914 on an old seedling orange tree near Oroville, Cal. Later in the same summer, the disease was found in a number of commercial orchards in the northern districts of that State.

The disease is characterized by an apparent infection which takes place nearly always at the joint between the petiole or leaf stalk and the leaf blade. The leaf blade soon dies and the disease progresses downward to the twig, involving the bark and killing it in a circular area from  $\frac{1}{4}$  to  $\frac{1}{2}$  in. in diameter. When the twigs are small, girdling often results and the twig dies back to the point of infection. Large twigs and limbs seem to have a certain degree of resistance, the disease being confined to new growth and limbs not over 1 in. in diameter. Badly infected trees are said to be filled with dead brush from girdled twigs, and the dead twigs and leaves soon become covered with fungi. The disease does its chief damage by killing the fruiting brush and greatly reducing the bearing area of the tree.

As a result of preliminary investigations, citrus blast is believed to be due to bacteria.

Citrus blast, a new disease, R. W. Hodgson (Pacific Rural Press, 92 (1916), No. 6, p. 124).—An account is given of investigations carried on in 1915 on the newly recognized bacterial disease of citrus occurring in northern California, which, according to the author, was first observed in 1912.

Infection is apparently confined to the new spring growth and occurs chiefly at the junction of the petiole and blade of the leaf. It also occurs at the tips of the very young leaves and tender shoots. When once established, the disease is said to progress rapidly down the shoot toward the older wood, but only the new tender growth is affected. Young shoots are often killed back to the older wood, including a portion of the bark about the base of the infected shoots, and it is not uncommon to find branches several feet long with every node infected. Upon infection the leaves are said to turn pale yellow, then to darken in spots and wilt, and later to shrivel and dry, though still hanging to the shoot.

The disease appears to spread with remarkable rapidity, only a few days of favorable weather conditions being required for serious damage. As the dry

season approaches it is retarded, and in midsummer it seems to be entirely quiescent. The organism, which is a bacterium, does not appear to be able to penetrate into the wood, and in some cases the cambium is not killed. Where trees contain a large amount of weak growth in the interior this is badly attacked and the bark rots away, leaving the interior of the tree full of dead, white twigs which are very resistant to further decay.

Some experiments are said to have been begun for the control of this disease, employing the methods used in pear blight control in California.

A new bacterial citrus disease, H. A. Lee (U. S. Dept. Agr., Jour. Agr. Research, 9 (1917), No. 1, pp. 1-8, pls. 3).—In a contribution from the California Experiment Station the author describes a new disease of citrus trees which is endemic to the citrus regions of northern and central California, previous accounts of this disease having been noted above.

In the author's investigations, sections of fresh, diseased material showed a bacterial organism present en masse. The organism has been isolated and the disease produced by inoculation experiments. A technical description of the organism, *Bacterium citrarefaciens* n. sp., is given and its morphological and physiological characters are detailed at some length.

The cause of June drop of navel oranges, J. E. Cott and R. W. Hodgson (Univ. Cal. Jour. Agr., 4 (1916), No. 1, pp. 8-10, 27-29, figs. 5).—The authors give a brief preliminary report of studies on the shedding of young fruits by orange trees in spring, which was excessive in 1916 despite good conditions as regards both weather and soil.

The dropped fruits in practically every test developed Alternaria, the cause of black rot. This fungus, the spores of which are deposited on the stigma in some way not yet determined, grows down to the base of the orange, infecting the portions of the old mutilated style which are left between the main fruit and the diminutive secondary fruit which pushes up through it to form the so-called navel. Valencia oranges, in which the old style breaks away clean, do not suffer from black rot or from excessive June drop.

The resistance of the fruit restrains for some time the development of the fungus and the fruit may reach its maturity and ripen without developing outwardly the black rot, though infected with Alternaria. Experiment shows that when transpiration is rapid, as in dry weather or districts, water is drawn back from the fruits by the leaves. The enzyms produced by the fungus probably poison and weaken the leaf and other cell tissues of the plant, in particular causing the formation of a cork layer and leading to the fall of the fruit. It is suggested that the navel-end splits occurring in fruits in the interior valleys may also be due to Alternaria.

Experiments looking to the control of June drop are under way and the distribution of the fungus also seems to require further investigation.

Spraying for ripe rot of the plantain fruit, J. F. Dastur (Agr. Jour. India, 11 (1916), No. 2, pp. 142-149, Ags. 2).—It is stated that ripe rot (Glæosporium musarum) of the plantain, while affecting chiefly stored fruits, may also appear on young fruits, generally near the distal end, supposedly arising in most cases from early infection at the style. Although spores germinated in water do not survive desiccation, some of those remaining in the ascervuli may germinate after nine months.

Experiments for three years on a restricted scale appear to show that spraying only when the fruit is picked, or even after it is half grown, is useless, but Burgundy mixture used monthly is found to control the disease. However, as this tends to leave bluish specks on freshly sprayed fruits, the last spraying is more satisfactorily done with ammoniacal copper carbonate.

This keeps the fruit clean and free from bluish spots, although if used several times it spots the fruits at points where they are in contact. Cutting back must be careful and destruction of diseased parts must be thorough in order to avoid the saprophytic preservation of the fungus. The fruit must be carefully handled in order to avoid injury.

[Notes on some pineapple diseases], M. O. Johnson (Hawaii Sta. Rpt. 1916, pp. 23, 24).—A brief account is given of an investigation of a serious disease of pineapples known as the Kauai wilt. This is rather definitely associated with a certain type of soil, and it is thought, from a lack of lime in the ash of diseased plants, that the trouble may be in some way connected with soil acidity. Pot and field experiments have been begun to determine the effect of liming on this wilt.

A brief account is also given of the yellowing of pineapples on manganese soil, a more detailed report of which has been noted (E. S. R., 36, p. 850).

Rusts of cultivated trees and their treatment with lime-sulphur, L. SAVASTANO (R. Staz. Sper. Agrum. e Frutticol. Acireale, Bol. 25 (1916), pp. 10).— This bulletin gives a résumé of some results of observation and experimentation during 1912 to 1916, in connection with rusts of cultivated trees, including their characters, causal organisms, favoring conditions, spread, and treatments.

Carnation leaf spot in Italy, M. Turconi (Riv. Patol. Veg., 8 (1916), No. 1, pp. 1-4).—A carnation disease was observed in Italy in 1915, due to a fungus, which, from the morphological characters of its mycelium and fructifications, appeared to be Alternaria dianthi.

Sweet pea diseases and their control, J. J. TAUBENHAUS (Trans. Mass. Hort. Soc., 1916, pt. 1, pp. 131-143).—The author discusses the results of investigations dealing with root rot (Corticum vagum) of the sweet pea, Fusarium wilt (F. lathyri), stem or collar rot (Sclerotinia libertiana), Thielavia root rot (T. basicola), root knot or nematode disease (Heterodera radicicola), mosaic (unknown as to causation), powdery mildew (Microsphera alni), anthracnose (Glomerella rufomaculans), streak (Bacillus lathyri), physiological troubles ascribed mainly to soil conditions, certain insects which wound or weaken the plants or carry spores, bringing about infection, and control methods.

Oak mildew, T. A. C. Schoevers (*Tijdschr. Plantenziekten*, 22 (1916), No. 2-4, pp. 84-93).—This is chiefly a discussion of contributions, more particularly that of Neger (E. S. R., 33, p. 745), on the classification and host relationships of the fungus causing oak mildew. This organism is considered distinct from that causing gooseberry mildew.

White pine blister rust, J. S. Duff (Rpt. Min. Agr. Ontario, 1915, p. 22).— It is stated that early in 1915 an outbreak of white pine blister rust was reported to the department and, as a result, the importation of five-leaved pines into Canada from Europe and the sale of such pines was for the present prohibited. A survey gave evidences of the disease in the counties of Brant, Durham, Halton, Kent, Lincoln, Wellington, and Wentworth.

## ECONOMIC ZOOLOGY—ENTOMOLOGY.

Animal micrology, M. F. Guyer (Chicago: Univ. of Chicago Press, 1917, rev. ed., pp. XI+289, figs. 74).—This consists of practical exercises in zoological microtechnique.

Notes on some animal parasites in British Guiana, G. E. BODKIN and L. D. CLEARE, JR. (Bul. Ent. Research, 7 (1916), No. 2, pp. 179-190, pl. 1 figs. 3).—Notes are given on the more important animal parasites occurring in British Guiana.

More minor horrors, A. E. Shipley (London: Smith, Elder & Co., 1916, pp. XIV+163, figs. 50).—This sequel to the volume previously noted (E. S. R., 34, p. 251) deals with cockroaches, the bot or warble fly, the malaria and yellow fever mosquitoes, the biscuit weevil (Anobium paniceum), the fig moth (Ephestia cautella), the stable fly, rats, and the field mouse (Apodemus sylvaticus).

The domesticated silver fox, N. Dearborn (U. S. Dept. Agr., Farmers' Bul. 795 (1917), pp. 32, figs. 22).—This bulletin is based upon Department Bulletin 301, previously noted (E. S. R., 34, p. 180), and supersedes Farmers' Bulletin 328 (E. S. R., 20, p. 350).

Habits and food of the roadrunner in California, H. C. BBYANT (Univ. Cal. Pubs., Zool., 17 (1916), No. 5, pp. 21-58, pls. 4, figs. 2).—In a study of the roadrunner (Geococcyx californianus) the author has examined the contents of 84 stomachs of birds collected in southern California in 1911 and 1912 during every month of the year except March, and here reports at length upon the results.

The examinations showed that practically 90 per cent of the total food was made up of animal matter and that slightly less than 10 per cent was of vegetable material, nearly all of the latter consisting of the fruit and seeds of the sour-berry (*Rhus integrifolia*). Of the insects and certain vertebrates which composed the animal food 18.2 per cent were beetles, 36.82 per cent grass-hoppers and crickets, 7 per cent cutworms and caterpillars, 5 per cent cleadas and other hemipterous insects, 4.24 per cent ants, bees, and wasps, and 3.67 per cent scorpions, 3.73 per cent lizards, 1.56 per cent birds, 1 per cent a tiny cotton-tail rabbit, and 2.38 per cent two different species of wild mice.

The results seem to substantiate rather than alter published statements regarding the food of the roadrunner, little evidence having been obtained that it is detrimental to man's interests. The roadrunner never turns its attention to any sort of cultivated crops, but rather feeds upon insect and rodent pests which attack such crops, and destroys the hairy caterpillars, not commonly attacked by other birds.

The paper includes a review of the literature in connection with a list of 40 titles.

Insect behavior as a factor in applied entomology, C. G. Hewitt (Jour. Econ. Ent., 10 (1917), No. 1, pp. 81-94).—The annual address of the president of the American Association of Economic Entomologists.

Theories of hibernation, A. T. RASMUSSEN (Amer. Nat., 50 (1916), No. 598, pp. 609-625).—A general summary with references to the literature, of which a list of 83 titles is included.

Simple apparatus for insect photography, B. H. Walden (Jour. Econ. Ent., 10 (1917), No. 1, pp. 25-30, pl. 1).—The author gives a brief description of simple photographic apparatus and methods for field and laboratory work used in the entomological department of the Connecticut State Experiment Station.

Eighth annual report of the Quebec Society for the Protection of Plants from Insects and Fungus Diseases, 1915-16 (Ann. Rpt. Quebec Soc. Protec. Plants [ctc.], 8 (1915-16), pp. 116, figs. 30).—Among the more important entomological papers presented in this, the usual annual report (E. S. R., 34, p. 250), are the following: Some Aspects of Insect Behavior, by W. Lochhead (pp. 12-23); Apple Plant Lice and Their Control, by R. Matheson (pp. 24-41); The Chrysopa or Golden-eyed Fly, by J. C. Chapais (pp. 50, 51); Grasshoppers and Their Control, by A. Gibson (pp. 52-57); Insect Notes, 1915, by E. M. DuPorte (pp. 73-77); Three Injurious Acridians of Nova Scotia, by C. B. Gooderham (pp. 89-91); and Insect Pests of Cereal Crops of Quebec, by W. Lochhead (pp. 101-115).

The principal insect pests and plant diseases, V. A. HUARD (Min. Agr. Prov. Quebec Bul. 23 (1916), pp. 75, figs. 78).—This paper, which is in the French language, consists in large part of accounts of the more important insect pests of the Province.

Garden and truck crop insect pests, C. E. Sanborn (Okla. Agr. Col., Ext. Div. Circ. 41 (1916), pp. 76, figs. 78).—This is a popular account of the more important insect enemies of truck and garden crops in Oklahoma.

Potato insects, M. A. Yothers (Washington Sta. Popular Bul. 106 (1917), pp. 96-123, figs. 17).—This is a brief descriptive account of the more important insect enemies of the potato in Washington, with directions for their control. Those mentioned as affecting the foliage are the apple leaf-hopper, blister beetles (Epicauta maculata and E. oregona), the Colorado potato beetle, cutworms, grasshoppers, the potato aphis (Macrosiphum solanifolii), and the tobacco worm. The insects, etc., which affect the tubers include the sand cricket (Stenopelmatus sp.), wireworms, and eelworms (Heterodera spp.). Those which affect both foliage and tubers are the potato flea beetle (Epitrix subscrinita), the potato tuber worm, and the twelve-spotted cucumber beetles (Diabrotica soror, D. 12-punctata, and D. 12-punctata tenella).

South American crickets, Gryllotalpoidea, and Achetoidea, L. Brunes (Ann. Carnegie Mus., 10 (1916), No. 3-4, pp. 344-428).—This paper contains descriptions of a number of apparently new forms.

Notes on the black apple leaf hopper (Idiocerus fitchi), W. H. BRITTAIN and L. G. Saunders (Canad. Ent., 49 (1917), No. 5, pp. 149-153, pl. 1).—This leaf hopper, originally described from New York State, apparently occurs quite generally throughout the northeastern United States and Canada and is said to be very common throughout the Annapolis Valley of Nova Scotia. While considered by many farmers a pest of some importance, observations indicate that the injuries attributed to it have largely been brought about by other causes.

Technical descriptions of its several stages and brief notes on its life history are given.

Additions to the list of Missouri Cicadellidæ, E. H. GIBSON (Canad. Ent., 49 (1917), No. 2, pp. 75, 76).—Supplementary to the paper previously noted (E. S. R., 35, p. 463).

Three new species of Jassoidea from Missouri, E. H. Gibson (Canad. Ent., 49 (1917), No. 5, pp. 183, 184).—The three new species here described supplement the lists of Jassoidea occurring in Missouri noted above.

The bay flea louse, Trioza alacris, as a new pest in New Jersey, H. B. Weiss (Canad. Ent., 49 (1917), No. 2, pp. 73-75).—This psyllid has been present in several greenhouses in New Jersey for the past several years, but not until recently has it increased sufficiently to disfigure seriously its host plant, Laurus nobilis.

Further data on the relation between aphids and fire blight (Bacillus amylovorus), J. H. Merrill (Jour. Econ. Ent., 10 (1917), No. 1, pp. 45-47, pl. 1).—In further observations (E. S. R., 34, p. 452), the author finds blight to develop only in the tender succulent growth on the twigs. By hatching from eggs laid in blight cankers the aphids come in contact with the fire blight organisms, and can and do inoculate trees with the bacteria of fire blight. It appears that the amount of fire blight infection in an orchard may be materially decreased by destroying all of the aphids which may appear there.

Synopsis of the genus Saltusaphis, A. C. Baker (Canad. Ent., 49 (1917), No. 1, pp. 1-9, pls. 2, figs. 17).—Five members of this genus which live on sedges and in marshy localities are recognized as occurring in America, three of which are here described as new.

The California species of Myzus, with the description of a new species, G. O. Shinji (Canad. Ent., 49 (1917), No. 2, pp. 49-51, fig. 1).—Seven species of this important genus are recognized from California, of which one (Myzus godetiæ) is described as new to science.

Mealy bug control, R. S. Woglum (Cal. Citrogr., 2 (1917), No. 4, pp. 4, 5, figs. 3).—This is a report of an address delivered before the Lemon Men's Club, at Alhambra, Cal., on January 3, 1917. The effect of fumigation on the citrus mealy bug, sprays effective against it, and important natural enemies, the interrelation of ants to mealy-bug infestation, etc., are discussed.

A list of the Coccidæ of Porto Rico, T. H. Jones (Jour. Bd. Comrs. Agr. P. R., 1 (1917), No. 1, pp. 1-16).—This is an annotated list of 50 species of the Coccidæ recorded from Porto Rico. A bibliography of 25 titles is included.

A new scale insect affecting sugar cane in New Guinea, A. RUTHEBFORD (Proc. Linn. Soc. N. S. Wales, 41 (1916), pt. 2, pp. 215, 216).—Under the name Aulacaspis major the author describes a new coccid occurring on the stems of sugar cane in New Guinea.

The development of the silk glands in the chief races of silkworms and in their first crosses, from the point of view of the quality and length of the reelable silk from each cocoon, P. Bucci (Staz. Sper. Agr. Ital., 48 (1915), No. 12, pp. 841–888; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 2, pp. 261–265).—Experiments repeated during 1914 and 1915 led to the conclusion that the weight of the adult worm in the nine races studied varies from 6,000 to 8,000 times that of the silkworm at the time of emergence from the egg. The lengths of the thread and the reelable silk of some of the races and hybrids are given. In each of the races studied the ratio between the average length of the reservoir and the average total length of a cocoon is always greater than 1:2.5. There is a correlation between the average weight of an adult silkworm, the average length of the silk gland, the absolute weight of the reelable silk of a single gland, and the average length of the reelable silk.

Genetic studies on the silkworm, Y. TANAKA (Jour. Col. Agr. Tohoku Imp. Univ., 7 (1916). No. 3, pp. 129-255, pls. 6, figs. 8).—A report of experiments carried on from 1910 to 1915 which relate particularly to the larval characters. A bibliography of 108 titles is included.

The Lepidoptera of the Isle of Pines, being a list of the species collected on the island by J. L. Graf and G. A. Link, sr., in 1910 and 1912-13, W. J. HOLLAND (Ann. Carnegie Mus., 10 (1916), No. 3-4, pp. 487-518, pl. 1).—An annotated list of 109 species.

Hyponomeuta species and their control in Sweden, A. Tullgren (Meddel. Centralanst. Försöksv. Jordbruksområdet, No. 110 (1915), pp. 23, figs. 16; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 2, pp. 316, 317).—Hyponomeuta evonymellus is said to be most widely distributed in Sweden, where it has appeared in recent years on Prunus padus in such numbers as to cause serious injury. H. malinellus, H. padellus, and H. cognatellus are less common and never very injurious.

An outbreak of the eight-spotted forester, Alypia octomaculata, in New Haven, Connecticut, Q. S. Lowry (Jour. Econ. Ent., 10 (1917), No. 1, pp. 47, 48).—The author records an outbreak of this pest on grape at New Haven, Conn., in 1916.

Notes on the peach-tree borer (Sanninoidea exitiosa), G. G. BECKER (Jour. Econ. Ent., 10 (1917), No. 1, pp. 49-59, fig. 1).—These notes relate largely to the pupation, emergence, and habits of the moth in Arkansas.

The peach tree borer: Life history, habits, injuries, and control measures, J. L. King (Mo. Bul. Ohio Sta., 2 (1917), No. 1, pp. 23-28, figs. 2).—This brief summarized account of the peach borer includes a diagram which graphically illustrates its life cycle in Ohio, month by month.

The lesser peach tree borer (Synanthedon pictipes), J. L. King (Ohio Sta. Bul. 307 (1917), pp. 399-448, figs. 21).—The lesser peach tree borer is a native insect, first recorded from Pennsylvania in 1868, which is quite generally distributed throughout the eastern half of the United States. The native food plants consist of wild cherry, wild plum, knots of black-knot, and the Juneberry; its cultivated food plants include the peach, plum, and cherry. It prefers the peach and may be easily confused with the common peach tree borer, though in the field it may be recognized through its habit of working, as a rule, above the soil level on the trunks and branches of the tree.

"Complete life history studies show that the winter is passed in all stages of larval development except the first. The moths emerge in May, June, and July. The egg-laying period corresponds closely to the time the adults are on the wing. In Ohio, the early hatched larvæ from the spring brood may complete their growth and give rise to a partial second generation, or summer brood. The adults of the second generation are on the wing from July to September. The larvæ from this brood of moths pass the winter as very small larvæ."

Serious injury by this species seems to be locally distributed. In Ohio the older peach-growing district of the Ottawa County peninsula and Catawba Island is very generally infested. Control measures consist in avoiding all mechanical injuries as scraping or barking during cultivation, improper pruning, or careless thinning or harvesting of the fruit. Timely and systematic digging out of the larvæ in the late fall and again in late May or early June is recommended. Sprays and repellent washes have proved of little or no value as a control.

A bibliography of 53 titles is included.

The head capsule and mouth parts of Diptera, A. Peterson (III. Biol. Monogr., 3 (1916), No. 2, pp. 112, pls. 25).—This report of anatomical studies is profusely illustrated by pen drawings.

The response of the house fly to certain foods and their fermentation products, C. H. RICHARDSON (Jour. Econ. Ent., 10 (1917), No. 1, pp. 102-109).—
The experiments here reported, which relate to solutions of known chemical compounds found in certain foods or their fermentation products which are eagerly sought by house flies, form a part of a larger project on the response of the house fly to environmental factors undertaken by the New Jersey Experiment Stations, accounts of which have been previously noted (E. S. R., 36, pp. 156, 460). The following conclusions are drawn from these experiments:

"Glucose, fructose, maltose, lactose, sucrose, starch, and dextrin were not very attractive to house flies. Lactose and dextrin caught the largest number of flies, starch the least. Sucrose was consistently a poor bait. Four per cent amylic alcohol gave better results than ethyl alcohol, or acetic acid in 4 or 10 per cent concentrations, and better than 10 per cent amylic alcohol. Four per cent ethyl alcohol was better than 10 per cent, 10 per cent acetic acid gave better results than 4 per cent. Succinic and lactic acids showed some attractive qualities in two experiments. Maltose, lactose, sucrose, and dextrin in 4 per cent solutions of amylic alcohol, ethyl alcohol, and acetic acid were more frequently visited by house flies than the corresponding aqueous solutions. Maltose and dextrin solutions were more effective than lactose or sucrose.

The order of response to the alcohols and acetic acid containing carbohydrate was the same as that for the aqueous solutions of these compounds.

"Crude gluten from wheat flour was not attractive. The water-soluble portion with or without starch in suspension was decidedly attractive. Several experiments with milk indicate that fat-free caseinogen is attractive, while butter fat is not. Experiments indicate that aqueous solutions of wheat flour and molasses to which sodium arsenite and amylic alcohol are added have considerable value as poisoned baits for house flies."

Biological note on Rhacodineura antiqua (not Ceromasia rufipes), a tachinid parasite of earwigs, J. Pantel (Bul. Soc. Ent. France, No. 8 (1916), pp. 150-154; abs. in Rev. Appl. Ent., Ser. A, 4 (1916), No. 8, p. 324).—It is pointed out that in the previous papers on the habits of R. antiqua the author has incorrectly recorded it under the name C. rufipes. The species was first described by Rodzianko from south Russia, where it was observed to live singly in young forms of Forficula tomis. The adults have been obtained in Portugal and Holland. In the present paper the author considers its life history and habits.

Sarcophaga and allies in North America, J. M. Aldrich (Lafayette, Ind.: The Thomas Say Foundation, Ent. Soc. Amer., 1916, pp. 311, pls. 16; rev. in Science, n. ser., 45 (1917), No. 1158, pp. 240, 241).—In this work the author describes 145 species and varieties belonging to 16 genera, of which 9 genera, 95 species, and 6 varieties are described as new. The genitalia of 138 are figured.

Sheep maggot flies, II, W. W. and J. L. Froggatt (Dept. Agr. N. S. Wales, Farmers' Bul. 110 (1916), pp. 30, figs. 8).—This second paper (E. S. R., 34, p. 64) consists of a report of work carried out in the New England District during 1914-15 at the Government Sheep Fly Experiment Station.

On the fruit flies of the genus Dacus occurring in India, Burma, and Ceylon, M. Bezzi (Bul. Ent. Research, 7 (1916), No. 2. pp. 99-121).—Twenty-six species of Dacinæ representing nine genera are noted of which one genus, eight species, and one variety are described as new. See also a previous note (E. S. R., 35, p. 259.)

Wheat sheath miner, H. L. SEAMANS (U. S. Dept. Agr., Jour. Agr. Research, 9 (1917), No. 1, pp. 17-25, fig. 1).—This is a report of investigations carried on at the Montana Experiment Station.

During the investigations in 1915 of wheat plants supposed to be infested with the greater wheat stem maggot (Mcromyza americana), a whitish larva was found associated with the greenish larva of M. americana. This proved to be Cerodonta femoralis, concerning which very little has previously been known, and further investigations have shown that it was largely responsible for the damage to the wheat plants. Records of its occurrence indicate that the species is generally distributed in the Northwest and infests winter wheat, spring wheat, oats, and timothy. Technical descriptions are given of its several life stages.

The injury caused by the wheat sheath miner appears to be identical with that of the stem maggot until the leaves are examined. It is stated that in each case the larva enters the leaf sheath by mining down from the point in the leaf where the egg was deposited. If the injury is due to *C. femoralis* the mine in the leaf is narrow, clean cut, and almost straight, while if it is done by *M. americana* it is broad and irregular with indistinct edges. While *M. americana* enters the stem and eats out the central stalk, usually cutting it off above the first node, *C. femoralis* confines its attack to mining up and down the leaf sheath and sometimes girdling the stem without completely cutting it off.

Whether it girdles the stem or not, the injuries caused by mining in the sheath appear to be sufficient to kill the stalk. Some farmers estimated

that their yields in winter wheat were cut down at least 25 per cent in the season of 1915, while in 1916 a field of spring wheat was visited which by actual count showed 95 per cent of the plants to have been injured by this insect. Some of the plants had only one culm injured while others had lost two or three. An adjoining field of oats is said to have had 12 per cent of its plants infested.

There is also said to be a slight amount of injury done to the plants, just before blossoming, by the second brood of larvæ. This injury is only to the leaves and probably has little or no effect on the yield as the central stalk does not appear to be injured.

In observations made at Bozeman the incubation period of the egg was found to be about six days under insectary conditions. Upon hatching out, the larva immediately starts mining down the leaf toward the stalk, eventually ending in the leaf sheath at the crown of the plant or at the first node. On reaching the base of the leaf sheath it feeds up and down the sheath and sometimes around the stalk. The length of the larval period is said to vary with climatic conditions, some of the larvæ pupating at the end of 10 days while others take as long as 20 days. The pupal period lasted about 25 days under insectary conditions. The adult flies appear about May 20 and lay eggs in wheat seedlings until about June 10. The flies of the second brood emerged in the insectary about July 16 and lived until August 5. The third generation of flies began to emerge September 7. The next generation is believed to hibernate as pupæ and produce the first brood of flies the following spring.

Two hymenopterous parasites were reared from puparia of *C. femoralis*, namely, a new braconid of the genus Dacnusa and the chalcidid *Cyrtogaster occidentalis*, but these do not occur in sufficient numbers to be effective agents in control. While control measures have not been tested, it is thought that a large percentage of the pests can be destroyed by scattering the straw over the field and burning the stubble as well as the grass borders surrounding the field. Where this is not practicable, the stubble can be plowed under about 6 in. and harrowed just after removing the crop or before planting the spring crop. It is also thought that the late seeding of winter wheat, after a thorough destruction of volunteer wheat and grass, will help much in control.

The control of the round-headed apple tree borer, G. G. Becker (Jour. Econ. Ent., 10 (1917), No. 1, pp. 66-71).—The author's investigations in Arkansas have led to the conclusion that the protection afforded by white lead is not commensurate with the returns. Pruning compound is worthless as a borer protector, paper wrappers and wooden veneers, from first observations, appear to be impracticable, the cost of screening is too great, and the efficiency of asphaltum against the borer is not worth the risk of injury to the trees. Worming the trees during the months of August and in early September is deemed the most practical as well as the cheapest method for controlling the borer.

[Banana weevil borer in Jamaica] (Jour. Jamaica Agr. Soc., 20 (1916), Nos. 4, pp. 129-132, 145, 146; 5, pp. 168, 169; 12, pp. 478-481).—These papers relate to the banana weevil (Cosmopolites sordida) in Jamaica, an account of which by Ballou has been previously noted (E. S. R., 36, p. 158).

A new weevil attacking pineapples in Jamaica, G. A. K. Marshall (Bul. Ent. Research, 7 (1916), No. 2, pp. 197, 198, fig. 1).—Under the name Metamasius ritchiei the author describes a large black weevil which was found doing serious damage to pineapples in Jamaica. It is stated that this weevil made its appearance in the Above Rocks District, Jamaica, about four years ago and grew steadily worse until 1916, when it is estimated 75 per cent of the pines were lost.

The plants seem to be attacked at various points. Sometimes the root stock is bored, or again the fruit stalk is hollowed out and collapses. A favorite place of attack is the junction of the fruit and stalk, when the larva proceeds into the fruit and riddles it, or the heart may be attacked before the pineapple has shot above the leaves.

Another weevil occurring in pineapples, namely, *M. sericeus*, appears to be secondary, it being attracted from the surrounding bananas by the decaying pines killed by *M. ritchiei*.

Pineapples: New weevil injury in Above Rocks District (Jour. Jamaica Agr. Soc., 20 (1916), No. 8, pp. 316-318).—This paper gives an account of the injury to pineapples caused by Metamasius ritchiei above noted.

The pineapple black weevil, W. Newell (Quart. Bul. Plant Bd. Fla., 1 (1917), No. 2, pp. 47-50, fig. 1).—A brief account of the pest (Metamasius ritchiei) above noted in which the author calls attention to the danger of introducing it into Florida.

Diseases of the honeybee, L. Bahr (Meddel. K. Vet. og Landbohöjskoles Serumlab., No. 37 (1915), pp. 109, pls. 2, figs. 6).—Following an account of the bacteria which normally occur in the hive, the author gives summarized accounts of the various diseases, etc., of the honeybee.

The habit of leaf oviposition among the parasitic Hymenoptera, H. S. SMITH (Science, n. ser., 44 (1916), No. 1148, pp. 925, 926).—The observations here reported relate to Perilampus hyalinus, a hyperparasite of the fall webworm, and are in continuation of those previously noted (E. S. R., 27, p. 261).

In connection with observations of this species, which was occasionally reared at Sacramento, Cal., from Chrysopa cocoons, the author secured several adult female Perilampus hovering about oleanders infested with *Aphis nerii* and fed upon by Chrysopa. The author has found that the eggs are deposited on the leaf, thus establishing beyond doubt the habit of leaf oviposition among parasitic Hymenoptera. The eggs are numerous, one female having deposited 52 in a single day. They hatch in from seven to ten days, and the first-stage larva, which is of the planidium type, is active at first, crawling rapidly about, but later attaches itself to the leaf by the caudal end, then standing out at right angles to the surface, where it awaits the approach of the Chrysopa larva, to which it attaches.

A new genus of omphaline Eulophidæ from North America, A. A. GIRAULT (Entomologist, 49 (1916), No. 642, pp. 249, 250).—Miromphalomyia perilampoides n. g. and n. sp. is described from Arizona.

The North American species of Habrocytus (chalcid flies), A. A. GIRAULT (Canad. Ent., 49 1917), No. 5, pp. 178-182).—A table based upon the females is given of ten species of Habrocytus recognized as occurring in the United States, and six species and one variety are described as new.

Notes on coccid-infesting Chalcidoidea, I, J. WATERSTON (Bul. Ent. Research, 7 (1916), No. 2, pp. 137-144, flgs. 3).—Diversinervus silvestrii reared from Lecanium viride on coffee in Mauritius and Coccophagus acanthosceles from the body of Lecanium sp., Singapore, Straits Settlements, are described as new.

Search for melon fly parasites, D. T. FULLAWAY (Hawaii. Forester and Agr., 13 (1916), No. 8, pp. 303-306).—The author reports upon a trip made to Singapore, Java, and India in search of parasites of the melon fly. The parasite discovered, Opius fletcheri, was found to occur in all three localities, particularly in India, from whence it has been introduced by the author into the Hawaiian Islands.

During the course of several months spent in the Philippine Islands rearing the parasites, the author's attention was called to the heavy parasitism of the corn leafhopper. An attempt made to introduce these parasites into Hawaii failed,

A new species of Amphrophora from California, G. O. Shinji (Canad. Ent., 49 (1917), No. 2, pp. 51, 52, fig. 1).—Amphrophora cicutæ reared from wild and cultivated blackberry is described as new to science.

A contribution to the knowledge of the mites attacking wild and cultivated plants in Sweden, I. Trägårdh (Meddel. Centralanst. Försöksv. Jordbruksområdet, No. 109 (1915), pp. 60, figs. 20; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 3, pp. 463, 464).—This account relates to various species of Neotetranychus, Paratetranychus, and Tetranychus which are a source of injury in Sweden.

Ascaris canis and Ascaris felis.—A taxonomic and a cytological comparison, A. C. Walton (Biol. Bul. Mar. Biol. Lab. Woods Hole, 31 (1916), No. 5, pp. 364-372, pl. 1, figs. 6).—The most important points brought out in the study are summarized as follows:

"Material used is same as recognized European forms of A. canis and A. felis. A. canis shows 18 chromosomes for the haploid number, 12 di-tetrad autosomes, and 6 tetrad idiosomes. These 6 tetrad idiosomes form a heterosome group of the X-type. There are two types of second spermatocytes and spermatids found, one type having 12 autosomes and 6 idiosomes, the other type having but the 12 autosomes. In A. felis there are 9 chromosomes in the primary spermatocytes, 8 autosomes, and one large heterochromosome composed of unequal parts. This is in agreement with Edwards. A. canis and A. felis are morphologically and cytologically two different species, not varieties of the same species. Chromosomes of true A. canis do not agree in form or number with those described by Marcus for his so-called A. canis."

On the life cycle of some cestodes, C. Joyeux (Bul. Soc. Path. Exot., 9 (1916), No. 8, pp. 578-583).—An account of the life cycles of three cestodes, namely, Dipylidium caninum, Hymenolepis diminuta, and H. nana siebold, for which insects play the rôle of intermediate hosts.

### FOODS-HUMAN NUTRITION.

The dietary deficiencies of the white bean, Phaseolus vulgaris, E. V. McCollum, M. Simmonds, and W. Pitz (Jour. Biol. Chem., 29 (1917), No. 3, pp. 521–536, pl. 1, figs. 9).—This paper presents the results of experiments in which laboratory animals (rats) were fed the white bean as the principal constituent of the diet and also the bean supplemented in various ways with purified food factors. The following facts were brought out in these experiments:

There was a high mortality and pronounced stunting of growth in animals fed a ration which contained 19.8 per cent of proteins, all derived from the bean. The addition of 3 per cent of casein improved noticeably the condition of the animals, but this is attributed by the authors to the casein itself rather than to any marked increase in the value of the beans through the supplying of a particular amino acid present in very small amount in bean proteins and plentiful in casein.

A high content of beans in the diet apparently had an injurious effect on the rats. Animals fed a ration containing 45 per cent of beans were better nourished than others receiving a ration which contained 70 per cent of beans, each ration containing 9 per cent of casein. Animals receiving a ration containing 50 per cent of beans with 4 per cent of casein were better nourished than another lot, the ration of which contained 86.3 per cent of beans and 3 per cent of casein. Two possible explanations of this are offered. One is that the beans contain some unknown chemical complex which is harmful when ingested

in large amounts, but the more plausible is that the rats are mechanically injured by the distention of the digestive tract, due to the fermentation of the hemicelluloses contained in the beans.

The white bean appeared to be even poorer in its content in the dietary factor "fat-soluble A" than are the cereal grains. It was found that the inorganic content of the bean is not of the character which supports growth. The bean was found to contain an abundance of the unidentified diet factor "fat-soluble B," and 25 per cent of beans in the diet, as the sole source of this factor, supported completion of growth and repetition of reproduction.

The authors state that their experiments furnish conclusive evidence that the entire protein mixture of the bean is of low value, although further inquiry must be made to show which amino acid is the limiting factor, and that the bean proteins are decidedly inferior to those of meat, milk, eggs, and the cereal grains (wheat, maize, oat, and rice kernels) which they have studied. It is pointed out that the frequent recommendation for the substitution of legumes as a class for the apparently more expensive sources of protein, such as meat, milk, and eggs, may be misleading and that, owing to the extensive fermentation of the carbohydrates of beans, this legume should not form a principal part in a relatively monotonous diet such as is furnished the inmates of many institutions in this country.

From the data of these and earlier experiments on the feeding of the cereal grains the general conclusion is drawn that "the great problem in practical dietetics and in animal production lies not in securing enough of the unidentified chemical complex associated with the causation of polyneuritis ('water-soluble B') but in securing a satisfactory adjustment among (1) the digestion products of the proteins of the diet (amino acids), (2) an adequate supply of the 'fat-soluble A,' and (3) more important even than a high biologic value of the protein mixture of the ration, a content of the essential inorganic elements suitable in amounts and proportions."

Extensive experience in feeding natural food substances restricted to a single source has shown that the character of the inorganic content of the food mixture, if fed monotonously, constitutes a factor of the greatest importance in influencing the growth and well-being. Furthermore, as small amounts as 15 per cent of wheat kernel, 3 per cent of wheat germ, or 25 per cent of thoroughly cooked beans will supply an ample amount of all of the unidentified food essentials except that supplied by butter fat ("fat-soluble A").

The authors state that the tendency to regard scurvy, pellagra, rickets, and other types of malnutrition as being due to the lack of a specific chemical complex in the diet lacks convincing experimental proof. "Any diet containing a moderate content of a wholesome natural food will not be lacking in the 'water-soluble B'."

Corn as a source of protein and ash for growing animals, A. G. Hogan (Jour. Biol. Chem., 29 (1917). No. 3, pp. 485-493, figs. 3).—These experiments constitute an extension of earlier work by the author (E. S. R., 36, p. 158). The object was to determine specifically what inorganic elements in the ash of the corn and what amino acids in its proteins are deficient in quantity and thus constitute limiting factors when the corn kernel is used as an exclusive diet. The experiments were conducted with laboratory animals (usually rats).

From the data reported the author concluded that the most important mineral deficiency of corn is calcium, and that tryptophan is the first and lysin the second limiting factor in the proteins of the corn kernel.

The soy bean in nutrition, Balland (Compt. Rend. Acad. Sci. [Paris], 164 (1917), No. 7, pp. 300-302).—Descriptions and analyses are given of some soybean products used in France. Among those used in the army are canned raw

soy beans, canned soy-bean soup, whole beans, soy-bean flour, and war bread and biscuit made with soy-bean and wheat flours.

The chemistry of bread making. J. Grant (New York: Longmans, Green & Co., 1917, 2. ed., pp. VI+230, pls. 4, figs. 35).—The earlier edition of this book has been noted (E. S. R., 31, p. 657).

The bread-fed man, H. SNYDER (Northwest. Miller, 110 (1917), No. 4, pp. 239, 240, 265).—This paper discusses the relative cost of bread as a food, and summarizes considerable information regarding the nutritive value of bread.

The sablefish [or] black cod, H. F. Moore (U. S. Dept. Com., Bur. Fisheries Econ. Circ. 23 (1917), p. 6, fig. 1).—A popular treatise on the food value of the sablefish, in which are included recipes for its preparation for the table:

The nutritive value of margarin and butter substitutes, J. C. DRUMMOND and W. D. HALLIBURTON (Jour. Physiol., 51 (1917), No. 1-2, pp. VIII-X).—This is a preliminary report of an investigation of the nutritive value of various commercial edible fats, data being here reported regarding margarin.

The authors state that their experiments with oleo-oil margarins have confirmed the results of other investigators and have shown these fats to be "quite able to replace butter in satisfying the nutritive requirements of the young rat." With reference to the vegetable-oil margarins, they state that their experiments thus far have shown that margarins prepared with a basis of coconut fat are not equal in nutritive value to butter or oleo-oil margarins.

Included in this study was a heterogeneous collection of butter substitutes which consisted of a basal vegetable fat with which was incorporated a greater or less proportion of crushed, dried nuts. The nutritive value of these products was found to vary considerably. One composed of the basal vegetable fat and dried walnuts was entirely unable to replace butter, while another preparation made from the same basal fat and crushed coconut fiber had a high nutritive value.

Two preparations, one apparently a deodorized coconut oil and the other probably a hydrogenated cottonseed product, were also examined. Both were found to be free from the fat-soluble accessory food substances.

The edible canna, M. O. Johnson (Hawaii Sta. Rpt. 1916, p. 25).—Analyses are reported of two samples of rootstalks of the edible canna (Canna edulis).

Caramels, A. McGill (Lab. Inland Rev. Dept. Canada Bul. 365 (1917), pp. 13).—This bulletin reports the results of an examination of 110 samples of caramels. Of these 51 were found to contain paraffin in amounts varying from 1 to 7 per cent by weight.

Fermentation of sauerkraut, L. A. ROUND (Amer. Grocer, 95 (1916), No. 7, p. 55).—In this address the author outlines the conditions necessary for the successful fermentation of sauerkraut.

The fermentation of sauerkraut, L. A. Round (Canner, 42 (1916). No. 9, p. 116).—This contains essentially the same information as that noted above.

Botulism, E. C. Dickson (*Proc. Soc. Expt. Biol. and Med., 14 (1916), No. 2, pp. 47, 48*).—In extension of earlier work (E. S. R., 33, p. 866) on the growth of *Bacillus botulinus* in vegetable medium, the author has found that corn and apricots are also suitable for the development of the toxin of the organism.

Report of division of food and drugs, H. C. LYTHGOE (Ann. Rpt. Dept. Health Mass., 1 (1915), pp. 433-534).—This report covers the work of the division for the year ended November 30, 1915, which included the inspection of slaughtering, dairy inspection, and the chemical examination of a large number of samples of milk, miscellaneous foods for adulteration, foods held in cold storage, drugs, poisons, etc. A list of legal actions taken and food confiscations is given. As an appendix is added a report by L. I. Nurenberg on dairy

products presented to the thirty-second convention of the Association of Official Agricultural Chemists at Washington, D. C., November 15, 1915.

Sixteenth biennial report of the Minnesota State Dairy and Food Commissioner, J. J. Farrell (Bien. Rpt. Minn. State Dairy and Food Comm., 16 (1915-16), pp. 114, figs. 3).—This publication reviews the work of the dairy and food division for the two years ended July 31, 1916. It also includes the results of the analyses of a large number of miscellaneous food products, reports of sanitary inspections, etc.

What to feed the children, Dobothy R. Mendenhall and Amy L. Daniels (Wis. Col. Agr. Ext. Serv. Circ. 69 (1917), pp. 10, figs. 5).—Suggestions are given for the feeding of healthy infants and young children.

Manual for army cooks, 1916 (War Dept. [U. S.], Doc. 564 (1917), pp. 270, pls. 3, figs. 33).—The first chapter of this manual contains definitions of a great number of culinary terms and later chapters are devoted to a consideration of the garrison ration, meat and fish, elementary principles of cooking and nutrition, management of the company mess, field cooking, and messing on railroad trains and transports. The manual contains descriptions of various types of cooking utensils and field and other cooking ranges, and a large number of recipes.

Reports of the executive committee of Mayor Mitchel's Committee on Food Supply, G. W. Perkins (New York: [City], 1914, pp. 20).—This is a preliminary report on the increase in price of foods, which is attributed to four important factors, namely, "the present and anticipated foreign demand for . . . [United States] domestic foodstuffs for future shipment; the heavy buying of household supplies by housewives against future needs; the holding back by the producer; and the stocking up by local storekeepers and village storekeepers—the latter class having made unusually heavy demands on the producers and wholeselers throughout the country."

The control of food supplies in blockaded Germany, A. E. TAYLOR (Saturday Even. Post, 189 (1917), Nos. 34, pp. 7, 8, 56, 59, 61, 64, 65, figs. 2; 35, pp. 18–20, 35, 37, 38, 41, 43, 46, 47, figs. 9; 36, pp. 25, 26, 49, 50, 53, 55 figs. 7).—This article gives an account of the measures developed by the German Government to combat the shortage of food resulting from the blockade and other phases of the war.

Food values in Belgium, H. Snyder (Northwest. Miller, 110 (1917), No. 2, pp. 96, 117).—This is a review of a pamphlet by R. Smith, which presents data regarding the foods used, their cost and nutritive value, and the distribution of supplies in the work of the Commission for Relief in Belgium.

The physiology of food and economy in diet, W. M. Bayliss (London: Longmans, Green & Co., 1917, pp. VIII+107).—The first chapter of this book considers briefly the problem of food as a whole. Later chapters are devoted to the uses of food, the quantity of food required, accessory food factors, digestibility, value of cooking, characteristics of certain articles of the diet, possibilities of economy, etc. A list of references concludes the publication.

The desire for food in man, MINNA C. DENTON (Sci. Mo., 3 (1916), No. 6, pp. 557-568).—The author analyzes, on the basis of recent experimental data, hunger and appetite, which are considered to be distinctly different motives in the desire for food.

The supplemental dietary relationships among our natural foodstuffs, E. V. McCollum (N. Y. Med. Jour., 105 (1917), No. 4, pp. 167, 168).—This is a summary of a lecture in which the author reviews briefly the results of his experiments which have been noted in full from their original sources.

[Progress in] physiological chemistry, F. G. Hopkins (Ann. Rpts. Prog. Chem. [London], 13 (1916), pp. 195-218).—A summary and digest of experi-

mental data contributed to the field of physiological chemistry during 1916. This includes the subjects of coagulation of the blood, anaphylaxis, hydrolysis of proteins, the importance of individual amino acids in nutrition, residual nitrogen of the blood, sugar of the blood, and renal permeability.

The hourly elimination of certain urinary constituents during brief fasts, I. Neuwirth (Jour. Biol. Chem., 29 (1917), No. 3, pp. 477-484).—The data here presented form a part of a contemplated study of the influence of various agents (chiefly foodstuffs) upon the elimination of certain urinary constituents, especially uric acid. The subject of the experiments was a normal male.

In experiments in which the quantity of the water ingested was low there was a marked fall in the uric acid output during the morning hours, followed by a more gradual decline during the afternoon. There was also an unmistakable relationship, within certain limits, between urinary volume and uric acid excretion. When a constant and fairly liberal quantity of water was ingested the excretion of uric acid was somewhat more regular than in experiments where the water intake was low or irregular.

The relation between uric acid elimination and the creatinin output was not quite so definite as that between uric acid and the total nitrogen. In a general way the creatinin elimination also paralleled the total nitrogen, but this relation was not so constant as for the uric acid. The experiments here reported showed that for short fasts the creatinin output may show marked hourly variations.

Proteose intoxications and injury of body protein.—I, II, G. H. WHIPPLE, J. V. COOKE, and T. STEARNS (Jour. Expt. Med., 25 (1917), No. 3, pp. 461-477, fig. 1; 479-494, fig. 1).—Two papers are presented.

I. The metabolism of fasting dogs following proteose injection.—The experiments here reported were carried out upon laboratory animals (dogs). The results of the observations may be summarized in part as follows:

The nitrogen elimination curve in a fasting dog, after proteose injection, showed a great rise in total urinary nitrogen. The apex of the curve generally fell during the second 24-hour period following the injection and might increase more than 100 per cent above the mean base-line nitrogen level. It did not fall promptly to normal, but declined slowly in three to five days or more toward the original base line.

II. The metabolism of dogs with duodenal obstruction and isolated loops of intestine.—These experiments indicated that dogs with isolated loops of small intestine showed evidences of intoxication. The total nitrogen elimination rose greatly above the normal minimum of the fasting period in the preceding experiments, indicating that the intoxication was associated with great destruction of body protein. The authors assume that the intoxications are associated with a definite proteose intoxication which is capable of initiating and continuing a profound injury of tissue protein, one indication of this protein inqury being this great rise in total nitrogen elimination.

Metabolism in gout, W. BAIN (Lancet [London], 1917, I, No. 13, pp. 494, 495).—Observations on four cases of gout showed that the excretion of calcium in the the urine was lower than exhibited normally. However, as is usually the case, most of the calcium was excreted in the feces.

The administration of calcium chlorid to individuals kept on a fixed diet caused a slight retention of nitrogen but did not affect the phosphorus metabolism. "The effect on total calcium metabolism was not constant. In one case a small negative calcium balance was transformed into a small positive one; in the other the positive calcium balance was reduced. In both cases the urinary calcium was not affected."

#### ANIMAL PRODUCTION.

Digestibility of sugars, starches, and pentosans of roughages, G. S. Fraps (Texas Sta. Bul. 196 (1916), pp. 5-36).—The investigations here reported pertain to the digestibility of the sugars, starches, and pentosans of the feeding stuffs used in experiments already noted (E. S. R., 27, p. 668). Tabulated data show the percentage composition of these constituents, their digestibility, and the composition and digestibility of the substances obtained by boiling in dilute acid and alkali.

The results of digestion experiments with sheep are given in the following table:

Coefficients of digestibility of the sugars, starches, and pentosans of Texas feeds.

Kind of feeding stuff.	Mono- sic- chi- rids.	Disac- cha- rids.	Starch.	Solu- ble pento- sans.	Re luc- ing sugar from hemi- cellu- lose.	Ma- terial ren- dered insol- uble by acids.	Solu- ble resi- due.	Nitrogen-free extract.

Chemical composition of fodder plants of the Province of Samara (Otchet Bezenchuk, Sclsk, Khoz, Opytn, Sta. 5 (1914), pp. 101-127).—Experiments covering a period of several years to determine the feeding value from the chemical composition of a number of fodder plants are reported. The analytical data are submitted in tabular form.

The general conclusion drawn is that the hays from the steppe have as high a nutritive value and are as valuable for feeding stuffs as the hays from other sections.

Low-grade cottonseed meal.—Warning sounded to purchasers of feeding stuffs, A. E. Perkins and R. I. Grady (Mo. Bul. Ohio Sta., 2 (1917), No. 2, pp. 41-45).—Attention is called to the prevalence of inferior cottonseed meal on the market during 1916, and the need is pointed out for a better State law for the control of feeding stuffs. Results are given of chemical and mechanical analyses of samples of two lots of cottonseed meal bought by the station. Both of these lots fell below guaranty, and one contained from 40 to 60 per cent of a material thought to be cottonseed hull bran.

Hydrocyanic acid in cassava, M. O. Johnson (Hawaii Sta. Rpt. (1916), pp. 24, 25).—Determinations were made of hydrocyanic acid in "bitter" and "sweet" cassava. The percentage of hydrocyanic acid in the samples tested varied from

0.006 to 0.025 in whole roots, from 0.007 to 0.021 in peeled roots, and from 0.015 to 0.042 in the peel of roots. In samples of the waste from cassava roots used in the manufacture of starch there was found to be 0.003 per cent of hydrocyanic acid in the waste from whole roots and 0.0008 per cent in the waste from peeled roots. These results indicate that cassava waste, if boiled before feeding, is safe for use as a hog feed. The author cautions against the use of cassava itself, however, for feeding unless the finely-divided roots are thoroughly boiled with two or three changes of water.

Stallion enrollment.—VI, Report of stallion enrollment work for the year 1916, with lists of stallions and jacks enrolled, H. E. McCartney (Indiana Sta. Circ. 58 (1917), pp. 182, figs. 25).—This reviews the work of the stallion enrollment board of the State during the year, gives facsimile reproductions of the certificates of registry recognized by the State stallion enrollment law, and lists the stallions and jacks enrolled in the State by breeds and counties.

Stallion registration and licenses for the year 1916, W. L. CARLYLE, L. L. LEWIS, and W. L. FOWLER (Oklahoma Sta. Circ. 42 (1917), pp. XVIII+105).— This first annual report of the Oklahoma State Live Stock Registry Board contains the text of the State live stock registration law and rules and regulations adopted by the board for its enforcement, and gives lists by breeds and counties of the stallions and jacks licensed in the State during 1916.

## DAIRY FARMING-DAIRYING.

The mineral metabolism of the milch cow; second paper, E. B. Forbes, F. M. Beegle, et al. (Ohio Sta. Bul. 308 (1917), pp. 451-431).—The objects of the experiments reported in this bulletin, in continuation of those already noted (E. S. R., 35, p. 481), were to learn whether mineral equilibrium can be maintained on rations containing the maximum amounts of mineral nutriment obtainable in common practical feeds; to determine the effects of large additions to these rations of calcium, magnesium, and phosphorus in supplemental form, as inorganic salts; and to ascertain the reason for the limited utilization of the mineral nutrients during ordinarily liberal food consumption.

Six Holstein cows were used in collection periods of 20 days, separated by ten-day intervals on the ration of the collection period to follow. The cows were all in their second, third, or fourth period of lactation. None was bred during this experiment. They were fed and milked four times daily at six-hour intervals. The milk yield varied from 38.7 to 58.35 lbs. per head daily.

In order to supply maximum amounts of calcium, magnesium, and phosphorus, the rations were based on a leguminous roughage (either clover or alfalfa hay), corn silage, cottonseed meal, linseed meal, and wheat bran. Corn meal was used as the principal source of carbohydrate. During the first period of the experiments the variable portion of the rations was the roughage—three cows receiving alfalfa hay and three clover hay. During the second period three of the cows received a double portion of salt. The rations were further varied during this period by giving calcium carbonate to two cows and bone flour to two cows.

Detailed tabular data are given of the average daily feeds consumed, milk produced, and live weights of cows; percentage composition and weight of constituents of feeds and milk; weight of constituents of urine and feces; daily intake and balances of minerals and nitrogen; minerals in daily rations computed to normal solutions; utilization and elimination of nitrogen; coefficients of digestibility of rations; and distribution of the outgo of elements among milk, urine, and feces.

"The prevailing belief that all animals which receive leafy forage as a considerable part of the ration consume and digest an abundance of mineral nutriment is shown not to be true in relation to cows during ordinarily liberal milk production. With rations of common practical foods, especially chosen to provide maximum supplies of the mineral nutrients, all calcium, magnesium, and phosphorus balances were negative, as in the previous year's work. With large increases in the calcium, magnesium, and phosphorus contents of these rations, through increased amounts of food consumed and through the addition to the rations of large amounts of calcium carbonate and bone flour, all calcium balances and all but one magnesium balance remained negative, but the phosphorus balances became positive. This work presents satisfactory evidence that in the selective improvement of milch cows we encounter limited capacities to digest calcium magnesium, and phosphorus, and inability to maintain their body stores of these elements before any such limitations are apparent in their ability to digest and to utilize the organic nutrients. . . .

"Doubling the usual sodium chlorid allowance did not improve the retention of calcium, magnesium, and phosphorus. Twenty-eight gm. (1 oz.) of salt per head and day, with a ration of common foods, provides enough sodium for cows producing 45 lbs. of milk per day. An allowance of 1 to 2 oz. of salt per head and day, in accord with the amount of milk produced, will cover all sodium requirements. Rations containing enough sodium to meet the cow's needs commonly contain a larger proportionate supply of chlorin.

"Enough potassium seems to have been supplied by all the rations studied.

A deficiency of potassium in normal rations, therefore, seems unlikely.

"The various circumstances which determine the path of outgo of absorbed nutrients are commonly without corresponding effect on the retention of these elements in the body. In some cases nearly all the sodium of the excreta was in the urine, while in others it was nearly all in the feces. The same may be said of chlorin. The elimination of sodium and chlorin in the urine is increased by high intake of these elements, by constipation, and by high water intake. Potassium in cows is commonly excreted in much larger proportion in the urine than in the feces, but in rations characterized by predominance of acid minerals, potassium was eliminated more largely in the feces.

"Calcium is excreted by cows almost wholly in the feces, but a predominance of acid minerals in the ration may cause slight increase in urinary calcium. Magnesium always exceeds calcium in the urine, but is contained in the feces in amounts usually about four times as great as in the urine.

"The excretion of phosphorus is characterized by much the same proportionate distribution as the excretion of calcium, except that urinary phosphorus may be much increased by general physiologic disturbance. Sulphur is normally excreted in the feces, in quantities three or four times as great as in the urine, but with high sulphur intake the urinary sulphur may equal the feces sulphur.

"There were no noticeable effects of the foodstuffs or the mineral supplements (sodium chlorid, calcium carbonate, or bone flour) on the amount or composition of the milk.

"Such variations in the balance of acid and basic mineral elements as occur in normal cow rations do not affect the retention of the mineral elements in unmistakable ways. Evidence was obtained showing that negative balances of the mineral nutrients may signify either deficient intake of the same or the throwing off of previously absorbed stores in the face of continued superabundant supplies. Either positive or negative balances may signify, under certain circumstances, only comparatively unimportant fluctuations in extensive reserves.

"The nitrogen compounds of rations containing alfalfa hay are more digestible than the nitrogen compounds of rations containing clover hay; they are more completely absorbed from the intestine, but are more largely eliminated in the urine. The greater digestibility of the alfalfa nitrogen, therefore, seems not to signify corresponding nutritive superiority. The percentages of utilization of the nitrogen compounds of rations containing clover and of those containing alfalfa were the same.

"The deficient utilization of the minerals by cows... has practical bearings in the malnutrition of the bones of cattle, which is not uncommon after seasons of drought and overstocking of pastures, particularly in regions of unfertile, sandy soils or soils of granitic origin, especially if these be worn through long cropping with deficient fertilization. Further practical bearings are probably seen in the rather common failure of cows to breed after a season of forced milk production; also in the failure of many cows fed for high production to maintain high records during consecutive periods of lactation; perhaps also as a contributory cause in the usual shrinkage of milk flow, with advance in the period of lactation.... Thus far, under no circumstances, have we been able to cause calcium storage or to maintain calcium equilibrium."

Feeds for dairy cows, M. P. Jarnagin and O. T. Goodwin (Ga. State Col. Agr. Circ. 45 (1917), pp. 8, figs. 2).—The rations used in the experiments here reported consisted of a maximum and minimum feed of sorghum and Kafir-corn silage and a minimum and maximum feed of mixed concentrates, with a check ration of silage and cottonseed meal. Twelve cows were divided into three lots of four cows each and fed by the reversal system for 90 days in 30-day periods, so that each group received each of the rations for 30 days.

On a ration of 36 lbs. of silage and 6 lbs. of cottonseed meal per head daily, the cows lost an average of 5 lbs. each in weight during the 90 days, and produced 6.829.9 lbs. of milk and 335.99 lbs. of butter at a feed cost of \$49.35. On a ration of 36 lbs. of silage, 7 lbs. of peavine hay, and 5 lbs. of a mixture of cottonseed meal, wheat bran, and corn-and-cob meal (4:3:3), the cows produced 6,820.7 lbs. of milk and 327.84 lbs. of butter at a feed cost of \$61.20. Each cow lost an average of 9 lbs. in weight during the 90 days on this ration. On a ration of 12 lbs. of silage, 10 lbs. of hay, and 10 lbs. of the above grain mixture, the cows produced 7,078.5 lbs. of milk and 341.14 lbs. of butter at a feed cost of \$79.92. On this ration they lost in weight an average of 5.5 lbs. each during the 90 days. The prices per ton charged for feeds were for cottonseed meal \$27.50, wheat bran \$30, corn-and-cob meal \$23, hay \$14, and silage \$3.

[Feeding cows with the subcutaneous matter of skins intended for tanning], Gerlach (Deut. Landw. Presse, 43 (1916), No. 26, p. 229; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 7, p. 996).—Feeding experiments are reported with a subcutaneous material, glue leather—i. e., leather cuttings containing gelatinous matter and consisting, according to the author's analysis, of 14.72 per cent of water, 55.77 per cent of protein, 12.35 per cent of fat, and 10.06 per cent of mineral matter. Nine milch cows between the second and third months of lactation were fed by the reversal system for 63 days, the basal ration consisting of chopped forage, hay, beet-leaf silage, mangels, potatoes, wheat bran, and lupines with the bitter taste removed. In addition, one group received 3 kg. of linseed meal and the other 1.5 kg. of glue leather per head daily.

The animals at once took to the latter ration. The milk secretion was 10 per cent less during the first period and a little greater during the second period in the glue-leather group than in the linseed-meal group. The milk was a little richer in fat during both periods in the glue-leather group.

Dairy cattle feeding and management, C. W. LARSON and F. S. PUTNEY (New York: John Wiley & Sons, 1917, pp. XX+471, figs. 128).—This book, which is intended for students and others interested in dairy cattle feeding and management, has been prepared by the authors primarily to meet the need of a textbook to broaden the field of the ordinary lecture course. A brief bibliography follows each lecture and the appendix gives suggested practicum exercises.

Dairy farming, J. Michels (*Peebles, Wis.: Author, 1916, 8. ed. rev., pp. 300, figs. 89*).—This is a revised and enlarged edition of this text and reference book for dairy students and farmers (E. S. R., 26, p. 574).

Dairying in Denmark, J. J. Dunne (Better Business, 2 (1917), No. 2, pp. 127-162, figs. 2).—This review of the organization of the dairy industry of Denmark deals especially with the establishment and growth of cooperative creameries, butter shows, and the use of the statutory trademark for Danish butter.

Kerry and Dexter cattle as producers of milk and butter fat, C. S. Plumb (Amer. Kerry and Dexter Cattle Club Bul. 6 (1917), pp. 5-16, figs. 11).—Milk and milk fat records of Kerry and Dexter cows in America and England and notes on the weight of Dexter cattle are given.

The highest year's records reported in America are for Kerry cows 6,103.9 lbs. of milk containing 269.8 lbs. of fat and for Dexter cows 9.046 lbs. of milk testing 4.26 per cent fat. The Dexter cow Bognut of Waddington, in the Ohio State University herd, produced in 1913 6,261 lbs. of milk, the percentage of fat ranging from 4 to 5.6.

A score card for dairy cows, E. G. Woodward (Breeder's Gaz., 71 (1917), No. 5, pp. 210, 212, flg. 1).—Some of the defects of the breed score card for dairy cows are noted. A score card is given which has been prepared with a view to pointing out without too much detail the relation between the appearance of the cow and her various functions which are essential to production.

Relation between the quantity of milk formed and that obtained in milking, S. G. Zwart (Ztschr. Fleisch u. Milchhyg., 26 (1916), Nos. 15, pp. 231-234; 16, pp. 246-250; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 8, pp. 1139-1141).—The author reviews the literature and reports results of experiments on the relation of the quantity of milk formed and that obtained during the process of milking.

The experimental results failed to confirm the theory that the greater portion of the milk is formed during the interval between milkings. In reference to the theory that milk is chiefly formed during milking, it was repeatedly possible to inject into the udder all the milk and in some cases twice the quantity of milk previously drawn from the udder. From results obtained in attempts to determine by exact measurement the quantity of milk formed in the udder, the author concludes that, while there is great variation in normal cows in good condition of lactation, on the average the quantities of milk formed during the period of rest and during milking by hand are equal.

The influence of parturition on the composition and properties of the milk and milk fat of the cow, C. H. Eckles and L. S. Palmer (Jour. Biol. Chem., 27 (1916), No. 2, pp. 313-326).—In this paper, contributed from the Missouri Experiment Station, data collected in cooperation with the Dairy Division of the U. S. Department of Agriculture are presented on the effects of parturition on the composition of colostrum milk and milk fat as influenced (1) by milking the cow up to the time of parturition and (2) by the length of the period the cow is dry before parturition. The general characteristics of colostrum milk are discussed and shown in tabular form, minimum, maximum, and average values of the various constituents being given as found by various investigators.

In studying the effects of continuous milking on the composition of the colostrum milk analyses were made of the milk and milk fat of three pure-bred Jersey cows for a suitable length of time before and after parturition. length of time since the last paturition was normal for each animal. character of the rations was not identical, but was uniform for each cow throughout the experiment. It was found that parturition failed to exert the usual depressing influence on the percentage of lactose in each of the three cases, although the lactose content was somewhat below normal in the milk of two of the cows. In regard to case in no effect was noticed in the case of two cows, but there was a high casein percentage for the other cow. The composition of the milk fat was uniformly unaffected by parturition. Very abnormal fat constants followed parturition in the case of one cow, but the fat showed the same abnormalities in even more striking degree for several days before parturition. The most uniform effect of parturition was upon the albumin and globulin or heat-coagulable proteins of the milk. The percentages of these proteins increased very materially up to the time of parturition, reaching a maximum in the first milk drawn after parturition. However, the actual proportion of the total milk represented by albumin and globulin in the case of these three cows was far below the minimum value for heat-coagulable proteins of normal colostrum.

To secure data on the influence of the length of time the cow is dry on the composition of colostrum and milk fat, complete analyses were made of the milk and milk fat of four cows for the first two or three milkings following parturition. These cows had been dry for from 19 to 83 days. In the case of each of the animals the first milk was drawn within a few hours after parturition.

It was found that the abnormalities in composition of colostrum milk are in direct relation to the length of the period of dryness. All the colostrum samples showed a composition more or less characteristic of the first milk drawn after parturition, but this was particularly striking in the case of the cow which was dry 83 days. The percentage of total solids, protein, casein, heat-coagulable proteins, and ash was abnormally high in each case, while the percentage of lactose and fat was abnormally low. However, in the case of the cow dry 19 days, the milk was much less abnormal in composition, although it showed a protein, casein, and heat-coagulable protein content considerably above normal. The fat content of the colostrum milk of the cow which was dry 19 days was 4.43 per cent, which was slightly below normal for this cow. The colostrum milk of the cow that had been dry 83 days contained only 1.3 per cent of fat. The results of this experiment indicate that the length of the period of dryness had little if any effect upon the composition of the colostrum fat. In each case the fat showed the composition characteristic of colostrum fat, having a low saponification and Reichert-Meissl value and high melting point. The iodin value of the fats analyzed did not show the extremely high figure usually characteristic of colostrum fat.

Preliminary research upon the effect of extracts of certain endocrine glands upon the amount of milk produced by cows and goats, C. D'Alfonso (Indus. Latt. e Zootec., 14 (1916), Nos. 15, pp. 215, 216; 16-17, pp. 234, 235; 18, pp. 253, 254; 19, pp. 268 269; 20, pp. 286, 287; 21, pp. 302, 303, 305; 22, p. 316; 24, pp. 350, 351; [15] (1917), No. 1, pp. 7, 9).—This is a report of studies of the effect of the injection of extracts of the ovaries, testes, adrenal glands, thyroid glands, hypophyses, and mammary glands upon milk production in cows and goats.

The large numbers of Bacterium abortus var. lipolyticus which may be found in milk, Alice C. Evans (Jour. Bact., 2 (1917), No. 2, pp. 185, 186).—By the use of methods described in an earlier paper (E. S. R., 35, p. 674), B.

abortus developed in 17 out of 23 samples of milk plated on one dairy farm. In the milk of one cow there were 112,000 of these organisms per cubic centimeter. If the milk of the 23 cows on this farm had been mixed there would have been about 7,000 B. abortus per cubic centimeter, or approximately 28 per cent of the total number of bacteria. Detailed studies of cultures from 11 of the samples indicated that nine of them were B. abortus var. lipolyticus and two resembled the cultures from pathological material.

Milk and its hygienic relations, JANET E. LANE-CLAYPON (New York & London: Longmans, Green & Co., 1916, pp. VIII+348, pls. 8, figs. 21).—In this book the author presents a survey of investigations directly related to the hygienic and nutritional aspects of milk. The different phases of the subject treated include the general composition, organic and inorganic constituents, biological properties, and cellular content of milk; breast feeding; the nutritive value of raw and boiled milk for the young of the same and different species; raw and boiled cow's milk for infants; dried milk for infants; Barlow's disease and rickets in relation to heated milk; changes in milk during heating; pathogenic organisms in milk, with notes on milk-borne epidemics; sources of milk contamination; sanitary milk production; bacteria commonly found in milk and their thermal death points; pasteurization of milk; and pathogenic bacteria in butter and cheese. Appendixes deal with the development of the mammary function, the subsequent development of the organism in relation to the method of feeding in early life, the preservation of human milk, a comparison of mother's and boiled cow's milk for infants, milk depots of England, desiccation of milk, grading of milk, and destruction of bacteria in milk without the application of heat. Each chapter is prefaced with a popular summary and is followed by a bibliography.

City milk supply, H. N. Parker (New York: McGraw-Hill Book Co., 1917. pp. XI+493, figs. 63).—This book treats of milk and its production, transportation, and delivery to city milk consumers, and of the methods of control adopted to insure its purity. An extensive bibliography of the literature cited is given at the end of each chapter.

Milk, sanitary and otherwise, J. Waddell (Sci. Mo., 4 (1917), No. 2, pp. 155-164).—This is a general account of the composition, sanitary production, and use of milk; the changes taking place during the fermentation, pasteurization, and digestion of milk; and the production and use of certified milk for infants.

Oxygenated milk, C. G. Geulee (N. Y. Med. Jour., 104 (1916), No. 23, pp. 1092-1094, figs. 3).—A report is given of an experiment at the Presbyterian Hospital in Chicago on the treatment of milk by hydrogen peroxid by a process, which is described, similar to the Budde process (E. S. R., 14, p. 1009).

Bacteriological examinations indicated that the oxygenated milk was sterile, except in one instance when there were approximately 100,000 streptococci per cubic centimeter, whereas in the raw milk before treatment there were 3,250,000 bacteria per cubic centimeter. Raw milk was inoculated with known virulent strains of hemolytic streptococci and typhoid and diphtheria bacilli, and treated with hydrogen peroxid. Plated cultures of this milk remained sterile during 72 hours of incubation, while blood agar plates of the same milk previous to oxidation contained from 2,500,000 to 3,000,000 bacteria per cubic centimeter.

The chemical changes in milk due to oxidation were not definitely studied. It is stated, however, that no gross changes have been noted. The rising of cream and digestive processes, such as coagulation with rennin and the usual digestion with pepsin, occur as in raw or cooked milk. It was impossible to prepare buttermilk from oxygenated milk. During the use of this milk for

over a year in the infants' and children's wards and throughout the hospital, nothing developed which has been ascribed to a deleterious influence of the oxygenated milk.

Chemical quality of New York City market milk, L. P. Brown and C. V. Ekroth (Jour. Indus. and Engin. Chem., 9 (1917), No. 3, pp. 299-301, figs. 3).—This is a general discussion of data collected from various sources and having a direct bearing on the subject. The need of placing chemical standards for milk on a more rational basis is emphasized.

A note on the milk supply of Bangalore, A. K. Y. N. AIYER (Dept. Agr. Mysore, Gen. Ser., Bul. 7 (1916), pp. 11, pls. 7).—The author describes the present condition of the milk supply of the city of Bangalore, gives the fat contents of a number of samples of various grades of street milk, tabulates the milk and fat yields of Mysore cows, and suggests methods for the improvement of the local breed and the production of crossbreeds of dairy cattle and buffaloes for supplying the city milk trade.

A survey of dairy score cards, C. E. NORTH (Amer. Jour. Pub. Health, 7 (1917), No. 1, pp. 25-39).—Brief notes on the history, application, and general uses of dairy score cards are given, together with a careful consideration of their value, particularly as affecting the character of municipal milk supplies.

In the author's opinion the three essentials upon which clean milk production depends are proper milking, cooling, and sterilizing. "If we assume that dairy cows and dairy employees are free from disease, sanitary milk of the highest type can be produced by a strict adherence to simple but standard methods for carrying out the three above-mentioned operations." A new type of dairy score card, based upon these essentials, is presented.

The Babcock test, and testing problems, H. C. Troy (Cornell Reading Course for Farm, No. 118 (1916), pp. 117-144, pl. 1, figs. 14).—Directions are given for the use of the Babcock test in determining the fat content of milk, cream, skim milk, and buttermilk, together with practical problems relating thereto and notes on the use of the Babcock test in rural schools.

How to make creamery butter on the farm, W. J. and Mrs. McLaughlin (Owatonna, Minn.: Minnetonna Co., 1916, pp. 110, pls. 7, figs. 11).—A revised edition of this manual (E. S. R., 33, p. 577).

Pepsin in cheese making, C. Stevenson (Jour. Agr. [New Zeal.], 14 (1917), No. 1, pp. 32-34).—In experiments at Taranaki, by the dairy division of the Commonwealth, milk arriving at a cheese factory was divided equally into three vats. The milk in vat 1 was coagulated with pepsin, vat 2 with a mixture of pepsin and rennet, and vat 3 with rennet only. The pepsin was used at the rate of 2.5 dr. per 1,000 lbs. of milk, and the rennet at the rate of 3.5 oz. per 1,000 lbs. of milk.

The curd in vats 2 and 3 was ready for cutting in 30 minutes, while that in vat 1 required 10 minutes longer to firm sufficiently for cutting. No difference was observed between the curds of any of the vats as regards the development of acidity or otherwise during the whole process of manufacture, and the yield of cheese from each vat was practically the same. The loss of fat in the whey of the vat in which only pepsin was used showed a slight increase as compared with the other two vats. Fifteen weeks after manufacture no difference was noted between the cheese made with pepsin and that made with rennet.

Directions are given for the use of pepsin for cheese making.

Is the ripening of cheese influenced by its fat content? W. VAN DAM (Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefstat. [Netherlands], No. 20 (1917), pp. 21-26).—The work of Jensen on the influence of fat on the ripening of cheese (E. S. R., 17, p. 1010) is critically discussed. The conclusions drawn from the results of the work are considered not to be well founded.

From the study with Edam cheese reported it is concluded that independent of the amount of paracasein present the digestion (ripening) proceeds slowly until a definite concentration of split products is reached. This explains the fact of a larger percentage digestion of cheese material in a sample rich in fat than in a sample poor in fat. The stimulating action of the fat on the casein could not be determined.

The judicial problem of Camembert, F. Marre (Le Problème Juridique du Camembert. Paris: Editions Scientifiques Francaises [1915], pp. 141).—In addition to notes on the history, manufacture, composition, definition, and fat content of Camembert cheese, this book deals with the legal status of this cheese in France.

The "cracking" of Edam cheese, F. W. J. BOEKHOUT and J. J. O. DE VRIES (Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefstat. [Netherlands], No. 20 (1917), pp. 71-78, pl. 1).—The results of the study reported indicate that the use of saltpeter has very little effect in preventing the cracking of Edam cheese when Bacillus coli communis and B. lactis aerogenes are present with the butyric acid bacteria. The former organisms destroy the preservative before it can suppress the development of the butyric acid organisms.

# VETERINARY MEDICINE.

A text-book of the principles and practice of veterinary medicine, D. S. White (*Philadelphia: Lea & Febiger, 1917, pp. 484*).—This work, prepared for use as a textbook by students of veterinary medicine, is based upon the author's personal experience for over 20 years as a teacher of veterinary students.

The comparative resistance of bacteria and human tissue cells to certain common antiseptics, R. A. Lambert (Jour. Expt. Med., 24 (1916), No. 6, pp. 683-688).—This material has been previously noted from another source (E. S. R., 36, p. 177).

The prophylaxis of the infection of war wounds.—A comparative study of various antiseptics, H. Vincent (Compt. Rend. Acad. Sci. [Paris], 164 (1917), No. 3, pp. 153-156).—The antiseptic and germicidal value of sodium fluorid, sodium formate, zinc chlorid, calcium hypochlorite, boric acid, sodium borate, copper sulphate, ferrous sulphate, potassium permanganate, and iodoform was studied by noting the action of the substances on a bouillon culture of Bacillus perfringens.

All the substances except boric acid and sodium borate were found to be very active. Copper sulphate yielded excellent results. Sodium fluorid was also found to possess excellent germicidal properties, but possessed a certain toxicity. The most satisfactory antiseptic used was a mixture of 10 parts of fresh calcium hypochlorite and 90 parts of crystallized boric acid in aqueous solution. This antiseptic was also found to possess hemostatic properties.

The treatment of wounds in war by magnesium sulphate, A. E. Morison and W. J. Tulloch (Jour. Roy. Army Med. Corps. 27 (1916), No. 4, pp. 375-398, pls. 2).—"From the first series of experiments it appears that magnesium sulphate exhibits to a greater degree than do the other salts investigated the desirable property of interfering with the digestive activity of pus. This statement is made with reservation as the experimental methods that one is forced to employ are open to certain criticisms, and I suggest that the rate of epithelialization of the wounds treated would give a truer index of the property than does experimental investigation.

"Magnesium sulphate has not so markedly inhibitory an action on phagocytosis as one would expect, and, therefore, even if it be absorbed to a slight

extent, it would not have a deleterious influence on the process, while salt, being more readily absorbed, might well interfere with this function of the leucocytes.

"Experimental work in physical chemistry and pharmacology points to magnesium sulphate as the least absorbable of the readily soluble salts, while clinical evidence—absence of pain, etc.—points in the same direction. By virtue of the nonabsorption of magnesium sulphate the granulations produced are more compact than when a more readily absorbable salt is employed. The magnesium ion has a markedly inhibitory action on the growth of streptococci and *Bacillus coli*, and a slightly inhibitory effect on the growth of *B. pyocyaneus*. It has, however, no easily demonstrable influence in the concentrations examined on the growth of staphylococci, or on the diphtheroids investigated."

Platelets and the coagulation of the blood, V. Ducceschi (Arch. Ital. Biol., 64 (1915), No. 3, pp. 341-353).—In the study reported the addition of cocaine (2.5 per cent solution) to frog blood immediately after being drawn prevented its coagulation. It retarded the coagulation time about 24 hours in chicken blood and from 1 to 2 hours in dog's blood.

In equal amounts the cocaine prevents the agglutinating phenomenou of the platelets in frog and chicken blood and also arrests the morphological modifications which ordinarily occur. The same effect, although not so marked, is observed with dog blood. In cases where coagulation results even after the addition of the cocaine a marked retraction in the clot was observed.

From the results it is concluded that the first phase of the coagulation of the blood consists of an active reaction of the platelets (agglutination, adhesion to the surface contacts, and morphological modifications), and a mechanical and chemical stimulation caused by contact with the normal cardiovascular surfaces and the presence of the thrombokinase, stimulations which are ordinarily the cause of coagulation. This first phase of the coagulation appears to be paralyzed completely or partially by cocaine, which also retards the coagulation.

The separation of serum into coagulative and noncoagulative fractions, A. F. Hess (Jour. Expt. Med., 24 (1916), No. 6, pp. 701-708).—The coagulative principle of blood serum was found to be closely associated with the euglobulin fraction. A hemostatic containing about 2 per cent protein, which is more potent than the whole serum, has been prepared by the following procedure: The serum was saturated in the cold with pure crystals of sodium chlorid, filtered, and a small amount of chloroform added to the precipitate, which was then dialyzed for about a week. The dialyzate was taken up with Ringer's solution, and 0.3 per cent tricresol added. This solution was then filtered through a Berkefeld filter and bottled in 20-cc. vials.

The preparation has been employed in various manifestations of intractable hemorrhage, and has yielded most satisfactory results. When injected intravenously the euglobulin fraction is preferable, since a much smaller amount of foreign protein is introduced. It is also more quickly absorbed from the subcutaneous tissues.

While the exact way in which the substance exerts its coagulative effect on the blood was not determined "it would seem, in view of the fact that euglobulin is found in the normal blood, that it should be regarded as a physiologic coagulant, and its mode of action in these tests as merely an intensification of the normal clotting processes." Other globulins examined (egg and edestin from hemp seed) showed no coagulative power. That the coagulative effect of the euglobulin fraction was not due to a counteraction of antithrombin was evident from experiments in which the material was only partly able to overcome the inhibitory effect of hirudin.

Studies on anaphylaxis (antianaphylaxis), O. Thomsen (Overs. K. Danske Vidensk. Selsk. Forhandl., No. 5 (1915), pp. 363-413, figs. 3).—In the experiments reported sterilized horse serum was used as antigen in all cases and guinea pigs as the experimental animals. The sensitizing dose was given subcutaneously, the reinjection intravenously.

Animals sensitized on the same day and with the same dose, and thus considered to belong to the same group, reacted in a similar way as regards sensibility. Some differences, however, were observed between various groups of animals, although the dose was the same. The reason for this phenomenon is considered to depend in all probability on the season of the year and its effect on the production of the anaphylatoxin.

Sensitization was not found to remain unchanged indefinitely, as has been previously stated, but, while maintained in the beginning, a gradual decrease was observed. The guinea pigs reacted more and more weakly as they grew older. Very young animals (a few days old) are considered to produce a different antisubstance than those several months old (weighing from 300 to 500 gm.). Fully grown animals (from 800 to 900 gm.) appear to yield very weak antisubstances.

Antianaphylaxis is deemed subject to three phenomena: (1) The destruction of anaphylatoxin, (2) the prevention of the reaction between antigen and antisubstance, and (3) the reduction of the effect of the anaphylatoxin. The disappearance of the anaphylatoxin was found to depend to a great degree on the existing degree of sensibility. This has been determined by passive sensitization. Sensibility was found to rise very slowly with the increase of material used. The desensitizing influence of a sublethal dose of antigen was found to vary greatly, depending on the degree of the existing sensibility. Narcotics, peptones, urine, etc. were found to act as antisubstances by decreasing the rapidity of the reaction between antigen and antibody, in which case a larger dose of antigen was needed to produce shock. The effect of these substances was found to be much greater on weakly sensitized than on strongly sensitized animals.

Anaplasmosis.—The significance of intracorpuscular bodies, marginal points, and anaplasms found in the blood of sheep from Sardinia and Piedmont, G. Finzi and A. Campus (Nuovo Ercolani, 21 (1916), Nos. 30-31, pp. 493-500; 34-35, pp. 557-571; 22 (1917), No. 1-2, pp. 2-8; abs. in Trop. Vet. Bul., 5 (1917), No. 1, pp. 3-5).—The greater part of this work consists of a survey of the literature dealing with the subject of anaplasms.

On vitamins, amino acids, and other chemical factors involved in the growth of the meningococcus, Dorothy J. Lloyd (Jour. Path. and Bact.. 21 (1916), No. 1, pp. 113-130).—The study reported shows that the primary cultivation of the meningococcus in vitro is only possible in the presence of certain accessory growth factors present in blood, serum, milk, and other animal fluids, and probably also in vegetable tissues. These accessory factors were found to be moderately thermostable, soluble in water and alcohol, and rapidly adsorbed by filter paper but not by glass wool. "There is a relationship of the inverse order between the amount of amino acid present in the medium and the amount of vitamin required to stimulate the growth of laboratory strains, and it is therefore suggested that the action of the accessory growth factors is to increase the reaction velocity of the proteolytic metabolism of the meningococcus."

After isolation from the body the organism was observed to develop a change in its metabolism so that it became increasingly independent of the growth accessories in the medium, old strains requiring no additional vitamin supply if

an abundant supply of free amino acids was present. It is deemed probable that the main food requirements of the meningococcus are the amino acids.

Preliminary report on the relation of anaerobic organisms to forage poisoning, J. S. Buckley and L. P. Shippen (Jour. Amer. Vet. Med. Assoc., 50 (1917), No. 7, pp. 809-816).—The resemblance of this disease in the horse to that of botulism or sausage poisoning in man led the authors to conduct experimental work with Bacillus botulinus.

Experiments with a strain of this organism isolated from cheese showed it to possess intense toxin-producing powers. *B. botulinus* grown in modified Rideal-Walker broth produced death in both small laboratory animals and horses and donkeys. When grown in a medium containing dextrose instead of lactose, under strict anaerobic conditions, it was fully as potent to produce death in both small laboratory animals and horses and donkeys as when grown in the modified Rideal-Walker broth.

"While the few symptoms exhibited by the donkey and horses that succumbed greatly resemble some of the characteristic symptoms of forage poisoning, and while the post-mortem findings are yet more characteristic of this disease, it will require further research to establish a definite relationship to the natural or spontaneous so-called forage poisoning. Certain it is that *B. totulinus* is capable of producing a form of forage poisoning should conditions exist in nature for the development of the organism and the elaboration of its toxin as on pastures or in masses of feed material. We can see no good reason why such a development may not take place. Symbiosis is probably the rule rather than the exception in the development of anaerobes in nature."

Pulmonary strongylosis, W. B. Herms and S. B. Freeborn (*Jour. Amer. Vet. Med. Assoc.*, 50 (1917), No. 7, pp. 862-868).—This has been substantially noted from another source (E. S. R., 35, p. 182).

Anthrax (charbon), W. H. Dalbymple (Jour. Amer. Vet. Med. Assoc., 50 (1917), No. 7, pp. 831-846, figs. 5).—This paper, which was presented at the meeting of the Mississippi Veterinary Medical Association at Clarksdale, Miss., in January, 1917, relates particularly to the control and the possible eradication of anthrax. Data relating to the transmission of anthrax infection by insects, as based upon investigations by H. Morris at the Louisiana Experiment Stations, are briefly summarized.

Anthrax as an occupational disease, J. B. Andrews (U. S. Dept. Labor, Bur. Labor Statis. Bul. 205 (1917), pp. 155, pls. 11).—Though anthrax is primarily a disease of animals, such as cattle and sheep, from which it is transmitted to man in a number of industrial pursuits, the present work deals with it particularly as affecting man.

Vaccinations against hemorrhagic septicemia, II, J. B. HARDENBERGH and F. BOERNER, JR. (Jour. Amer. Vet. Med. Assoc., 50 (1917), No. 7, pp. 868-876).—Continuing the work previously noted (E. S. R., 35, p. 77), the authors have used the hemorrhagic septicemia vaccine in field work with promising results.

No standard animal test has been found for the vaccine other than that it is virulent for rabbits and guinea pigs, but not for sheep or calves. "Twenty-two recoveries among 23 vaccinated steers with but 12 recoveries among 25 native cattle on pasture seems to indicate a therapeutic value for the vaccine in chronic cases of hemorrhagic septicemia taking the form of pneumonia." Death within one week following vaccination of a few apparently healthy animals appears to indicate that sufficient immunity for protection is not developed within that time. It is indicated that the use of an antiserum simultaneously with a vaccine may eliminate such losses.

The work is being continued.

Transmission of pneumonic and septicemic plague among marmots, F. Ederson and Wu Lien Teh (Jour. Infect. Diseases, 20 (1917), No. 2, pp. 170-179).—In two series of experiments a total of 38 marmots was exposed to plague, resulting in the death of 23.

"Of the marmots placed in contact with marmots which had received inoculation by inhalation, 52.6 per cent developed pulmonary plague and died on an average within from four to six days. Early infectivity on the part of the inoculated animals and a short incubation period characterize the transmission.

"Pulmonary plague can be transmitted readily to the small marmot (Spermophilus citellus), and these animals are capable, in turn, of transmitting the same disease through the respiratory passages.

"Septicemic plague can be developed in marmots very easily as a result of respiratory infection, and also by direct subcutaneous inoculation with small amounts of culture. The marmot can take plague by way of the alimentary tract and can spread the disease by feeding on plague-infected carcasses. The microscopic lesions observed in these cases are characteristic."

A digest of the insect transmission of disease in the Orient with especial reference to the experimental conveyance of Trypanosoma evansi, M. B. MITZMAIN (New Orleans Med. and Surg. Jour., 69 (1916), No. 6, pp. 416-424).—This summary is based upon the author's experience in the Philippines, reports relating to which have been previously noted (E. S. R., 30, p. 780; 31, p. 777).

The complement-fixation test in the diagnosis of tuberculosis, C. F. CBAIG (Jour. Amer. Med. Assoc., 68 (1917), No. 10, pp. 773-776).—The recent work on the complement-fixation test in tuberculosis is reviewed.

Continued observations by the author have led him to conclude that the complement-fixation test is the most valuable diagnostic method that has as yet been devised for the early recognition of the disease and the best index of its activity. A positive reaction with the test is considered to indicate the presence of an active tuberculous focus, and as long as the reaction remains positive the patient should not be considered cured. While a single negative result with the test can not indicate a cure or absence of the disease, repeated negative results extended over a considerable period of time should be sufficient evidence that the infection is cured or that the disease is not present, especially in instances in which the diagnosis is doubtful.

Some experimental data are reported and discussed.

On the biochemistry of the loss of power of the tubercle "bacillus" to stain with carbol fuchsin, A. H. Miller (Jour. Path. and Bact., 21 (1916), No. 1, pp. 41-46, pl. 1).—From the study reported the variations encountered in the staining power of the tubercle bacillus with carbol fuchsin which has been grown on sperm and olive oil media depend upon the production of free oleic acid in the interior of the rod. This acid is considered to be formed by the round granules or spores of the organism.

The experimental procedures are described in detail.

Isolation of tubercle bacilli from sputum and determination of their type, Chung Yik Wang (Jour. Path. and Bact., 21 (1916), No. 1, pp. 14-22, pl. 1).—Of 29 strains of the tubercle bacilli isolated from sputum, 28 produced in the rabbit either no tuberculosis or a form similar to that produced by the bacilli of the human type. The remaining culture showed the well-marked characteristics of the "bovine" type and possessed a high virulence for rabbits.

A table showing the work on the subject by various investigators up to the present time is included. In 998 cases examined the human type was found in 991 instances, the bovine in 4, and 3 of the cases were mixed.

A bibliography of 21 references to the literature is appended.

An investigation of human bone and joint tuberculosis, A. S. GRIFFITH (Jour. Path. and Bact., 21 (1916), No. 1, pp. 54-77).—Of 155 cases of human bone and joint tuberculosis examined, 14 cases yielded negative results, 1 case was of multiple abscesses in the muscles, 4 cases were joint tuberculosis, in which cases the cultures were not isolated from the joint lesions but from tuberculous foci in other parts of the body, and in 136 cases cultures of tubercle bacilli were obtained from tuberculous bone or joint lesions. Of these cases 107 yielded human strains, 24 bovine, and 5 were atypical. The detailed clinical data and bacteriological results of the cases are reported in tabular form. The bacteriological characteristics of the tubercle bacilli isolated are discussed, and tabulated experimental data relative to experiments on the subcutaneous inoculation of rabbits with cultures isolated from various sources are reported.

The relative prevalence of human and bovine infection in bone and joint tuberculosis in different countries and at various age periods is discussed in some detail. The intimate connection between human and bovine tuberculosis and the danger to human beings, especially in childhood, of the consumption of living tubercle bacilli is emphasized. See also a previous note (E. S. R., 35, p. 576).

Some facts about abortion disease, E. C. Schroeder and W. E. Cotton (U. S. Dept. Agr., Jour. Agr. Research, 9 (1917), No. 1, pp. 9-16).—The data here presented have largely been noted from another source (E. S. R., 36, p. 881). The subject is dealt with under the headings of characteristics of the abortion bacillus, production of seemingly normal calves by infected cows, experimental infection introduced through the teat, the udder as a positive channel of infection, possibility of infection through the bull, and relation of the abortion bacillus to the embryo or fetus. The conclusions drawn are as follows:

"To prevent the further spread of abortion disease, owners of uninfected cattle should be instructed to have careful agglutination tests for abortion disease made of all cattle they propose to introduce into their herds; and owners of infected herds should be taught that aborted fetuses, also the afterbirth and discharge from the vaginas of infected cows, are infected with abortion bacilli and must therefore be disposed of with care.

"The treatment of individual cows which have aborted or failed to clean properly after parturition must be left largely to the good judgment of the practicing veterinarian. If the uterus is given a proper chance to heal after it has been damaged by an abortion or a retained afterbirth, the abortion bacilli in it need occasion little worry, as they will rapidly disappear of their own accord, and it is very questionable whether reparative processes are not retarded rather than facilitated by douching with germicidal solutions which are strong enough to kill bacteria in a reasonable length of time, or the length of time during which they may remain undiluted in the uterus. Douching is no doubt good practice, but it is desirable that there be a flooding out, a washing out, a real physical cleaning of the uterus; and this can best be done with solutions which are healing rather than germicidal, soothing, and not irritating."

Further investigations into the etiology of worm nests in cattle due to Onchocerca gibsoni, II, J. B. CLELAND, S. DODD, and E. W. FERGUSON (Melbourne, Aust.: Govt. [1917], pp. 41).—This communication gives the details of investigations carried on from 1913 to the end of October, 1915, in continuation of those previously noted (E. S. R., 32, p. 377), together with the deductions drawn. The authors summarize the results obtained and the views which they now hold in regard to the transmission of O. gibsoni as follows:

"Conveyance of O. gibsoni from one bovine to another in the open is still taking place at Milson Island. Experiments with large numbers of Stomoxys,

under conditions in which transference of Onchocerca might be expected to take place, supposing this insect to be the vector, failed to convey infection. This renders it apparently unlikely that S. calcitrans is the vector. Similar experiments of a less satisfactory nature with mosquitoes failed to convey infection. Transmission by mosquitoes can not, however, as yet be ruled out of court. A control calf protected in a fly- and mosquito-proof cage failed to become infected with Onchocerca. A calf, penned in an earthen floored cage, in the open, level with the ground, and exposed to the attacks of mosquitoes, Stomoxys, and tabanids showed the presence of a worm nest. In one of the stock animals examined, an arrested 'traveling' worm, 2.5 to 3 in. long, was found in a delicate fibrous tunnel. Circumstantial evidence appears to indicate that a tabanid may be the vector, which is supported to some extent by the apparent distribution of worm nests and of tabanids in Australia. Worm nests are more common in local cattle in the Sydney and Newcastle districts than was anticipated."

Shipping fever of horses, J. R. Mohler (Jour. Amer. Vet. Med. Assoc., 50 (1917), No. 7, pp. 817-823).—This paper, presented at the meeting of the American Veterinary Medical Association held at Detroit, Mich., in August, 1916, has been substantially noted (E. S. R., 36, p. 85).

Vesicular stomatitis contagiosa, J. Gregg, F. X. McGuire, G. J. Glover, A. Gillespie, and G. Greggry (Amer. Jour. Vet. Med., 12 (1917), No. 4, pp. 221, 222).—This account of the disease is based upon observations during the last four months of several thousand cases in horses and mules at the remount hospitals at Newport News, Va. The authors describe it as a contagious, febrile disease affecting horses and mules, with the principal pathological changes confined to the tongue, buccal mucous membrane, lips, and occasionally the nose. A large gram-positive micrococcus was obtained in pure culture by withdrawing the material, under aseptic conditions, from unruptured vesicles occurring chiefly on the tongue. One attack appears to render an immunity.

So-called staggers in horses caused by the ingestion of Pteris aquilina, the common bracken, S. Hadwen (Jour. Amer. Vet. Med. Assoc., 50 (1917), No. 6, pp. 702-704).—The death of many horses during January and February, 1916, from what farmers have commonly known as staggers led to an investigation. It appears that cases of this disease may be found in every country district along the banks of the Fraser River and on Vancouver Island. The author's experiments show that it can be reproduced by feeding bracken fern in both winter and summer, and the designation "bracken poisoning" is proposed for the affection.

A case of splenic abscess, secondary to invasion of the stomach wall of a horse by Spiroptera megastoma, C. G. Dickenson (Vet. Jour., 78 (1917), No. 502, pp. 14, 15).—The case here reported is said to be the first to come to the author's attention in which a splenic abscess has been found as a secondary infection.

Bacillary white diarrhea or fatal septicemia of chicks and coccidiosis or coccidial enteritis of chicks, J. R. Beach (California Sta. Circ. 162 (1917), pp. 8).—It is stated that in California coccidiosis is very prevalent while outbreaks of bacillary white diarrhea are comparatively infrequent. In none of the outbreaks of coccidiosis investigated by the station have there been any symptoms or history which might be confused with those of bacillary white diarrhea. In the present paper the author deals with the two diseases separately and attempts to describe them in such a manner as to avoid any confusion regarding their identity.

The use of bacterins in the control of fowl cholera, W. B. MACK and E. RECORDS (Nevada Sta. Bul. 85 (1916), pp. 3-29).—Eleven strains of Bacterium avisepticum isolated from outbreaks of fowl cholera in Nevada were found to possess a comparatively low degree of virulence for chickens in laboratory tests. "No strain behaved uniformly as to the time required to kill when inoculated into chickens; some birds failed to succumb to inoculation. The virulence for chickens could not be maintained by frequent passages through either rabbits or chickens; and no strain could be depended upon to kill by oral administration."

The bacterin was prepared by growing cultures of *B. avisepticum* on agar for 48 hours, washing with normal salt solution, and diluting to a content of 500,000,000 bacteria per cubic centimeter, or by growing in neutral plain bouillon. The organisms were killed by the addition of from 0.5 to 0.9 per cent phenol.

Three subcutaneous inoculations of the bacterin failed to immunize chickens against subsequent subcutaneous or intramuscular inoculations of the virulent organism. In 15 out of 16 lots of fowls in 14 flocks the use of the bacterin produced sufficient resistance to check promptly outbreaks of fowl cholera, although in one lot there was a recurrence requiring three treatments. The treatment of the other lot resulted in complete failure.

No apparent difference was observed in the use of homologous or heterologous strains of the organism in the bacterins. The use of a stock bacterin containing several strains appears to be satisfactory. It is indicated that "the value of a protective method must be judged by clinical rather than by experimental results."

The cultural characteristics, variation in virulence, and both laboratory and field inoculation data are submitted in tabular form.

The case of Trichomonas, P. [B.] Hadley (Amer. Nat., 51 (1917), No. 604, pp. 209-224, figs. 12).—Substantially noted from another source (E. S. R., 36, p. 483).

# RURAL ENGINEERING.

Irrigation enterprise in the United States: Introductory paper, C. E. Grunsky (Trans. Internat. Engin. Cong., 1915, Waterways and Irrig., pp. 342-370).—This paper outlines the various ways in which irrigation enterprises have been handled and constructed by landowners; by private owners, usually corporations, for profit; under the Desert Land Act; under the Carey Act; under the U. S. Reclamation Act; and under State irrigation district laws. Irrigation statistics and a bibliography are appended.

Present condition of irrigation in Argentina, C. Wauters (Trans. Internat. Engin. Cong., 1915, Waterways and Irrig., pp. 672-687).—This paper deals mainly with the legal, administrative, and economic phases of irrigation in Argentina.

Irrigation in Spain: Distribution systems, methods, and appliances, J. C. Stevens (*Trans. Internat. Engin. Cong.*, 1915, Waterways and Irrig., pp. 643-656, figs. 4).—This is a brief general description of distribution systems, methods, and appliances.

Irrigation in Spain: Regulations controlling the use of water, metering water for irrigation, and methods of charging, J. C. Stevens (*Trans. Internat. Engin. Cong., 1915, Waterways and Irrig., pp. 657-671*).—This paper deals with the regulations controlling the use of water, metering water for irrigation, and methods of charging.

Italian irrigation, L. Luiggi (Trans. Internat. Engin. Cong., 1915, Waterways and Irrig., pp. 530-582, figs. 35).—The author, in dealing with irrigation in Italy, concludes that "irrigation is decidedly most beneficial to the farmer.

Besides acting as an insurance against failure of crops in bad years, it generally doubles or more than doubles the normal crops, or it permits of the cultivation of crops of higher commercial value. It represents also a very important factor of progress for the district in which it is applied. But it is not equally beneficial for the corporations that carry out the irrigation works, because generally many years are required before all the water can be disposed of and thus there is a dead loss for a period of about 20 years, or even more, during which the State must grant some subsidy. . . . It is only just that the State should either carry out these works at its own expense or grant some substantial financial help to encourage irrigation projects."

A bibliography is included.

Irrigation in Libia, L. Luiggi (*Trans. Internat. Engin. Cong.*, 1915, Waterways and Irrig., pp. 583-590, figs. 4).—This is a brief general description of irrigation as practiced in Libia. It is stated that the future of Libia depends on the development of agriculture aided by irrigation.

The distribution of water in irrigation in Australia, E. Mead (Trans. Internat. Engin. Cong., 1915, Waterways and Irrig., pp. 611-642, pl. 1, figs. 7).—
The purpose of this paper is to describe the methods employed and the results obtained in distributing water for irrigation in Australia, special reference being made to water measurement devices.

Recent developments of irrigation in India, M. Nethersole (Trans. Internat. Engin. Cong., 1915, Waterways and Irrig., pp. 591-610, pls. 4).—This article enumerates the natural factors dominating irrigation progress in India, and describes irrigation methods and some of the more important irrigation works. Of the 220,000,000 acres annually cultivated in India, it is stated that about 41,000,000 are irrigated.

"The development of irrigation in [the decade ended with 1912], measured by the difference in the first and last totals, is about 25 per cent, while measured by the increase in the average for the last five years over that of the first five years of the period it is about 20 per cent. . . . The classification of the 41,000,000 acres irrigated in 1912 is approximately as follows: From government canals 42, private canals 5, tanks 13, wells 25, and other sources 15 per cent. . . .

"Irrigation from wells ranks in area and importance next to irrigation from government works. Irrigation wells are wholly the private property of the landowners, but construction is encouraged by the grant of temporary advances from public funds to the owners, which advances with interest at 4 per cent are recoverable by easy installments. The government further assists this class of irrigation by the loan to the owners of boring plants and the services of expert borers, both to make preliminary tests of the subsoil supply and to improve the supply in existing wells by tapping deeper water-bearing strata."

Economic advisability of irrigation, F. H. Newell (Trans. Internat. Engin. Cong., 1915, Waterways and Irrig., pp. 371-397).—It is pointed out in this paper that "irrigation is of prime economic importance to the community, State, and nation by enabling a complete agricultural development of the arid lands and by insuring immunity from loss by drought on other lands, thus making possible intensive cultivation and a maximum annual crop production. The material benefits to the community are not measured by the crop production alone, but by the stimulation of other industries, such as stock raising, mining, manufacturing, and transportation. A still greater benefit to the nation, rising far above material wealth, is that coming from the increase of an intelligent and prosperous rural population, who are not merely producers of food for other people, but who, living in the open, contribute most largely to the best elements of citizenship.

"The stagnation which now prevails in irrigation development is due to lack of proper recognition by engineers and investors of the fundamental economic conditions governing the profits of the individual irrigator, and can be relieved only when these conditions are more fully recognized and used as guides in future projects."

The utilization of ground waters by pumping for irrigation, G. E. P. SMITH (*Trans. Internat. Engin. Cong.*, 1915, Waterways and Irrig., pp. 414-457, figs. 7).—This paper has been previously noted from another source (E. S. R., 35, p. 787).

Distribution systems, methods, and appliances in irrigation, J. S. Dennis, H. B. Muckleston, and R. S. Stockton (*Trans. Internat. Engin. Cong., 1915, Waterways and Irrig., pp. 398–413*).—This paper consists of a discussion of the factors making for success in an irrigation system, which are enumerated as (1) a sufficient water supply, (2) good construction, and (3) a well organized system for transporting and delivering water to the settler. General features of design, construction, and maintenance of distribution systems are described. It is concluded "that the most important part of the distribution system is the farmer who is to use it. If the man is not successful, the project is a failure."

Duty of water in irrigation, S. Fortier (Trans. Internat. Engin. Cong., 1915, Waterways and Irrig., pp. 458-509, figs. 3).—The author discusses the legal, administrative, economic, and agricultural phases of duty of water in irrigation. The discussion is confined to the practice and conditions prevailing throughout the irrigated districts of the United States, and consists largely of a review and summary of the important features of investigations previously reported, especially those conducted under the author's supervision by the Irrigation Investigations of the U. S. Department of Agriculture.

Use of water in irrigation, S. Fortier (New York: McGraw-Hill Book Co., 1916, 2. ed., pp. XVI+325, pls. 12, figs. 77).—This is the second edition of this book (E. S. R., 32, p. 389) in which "the typographical and other minor errors of the first edition have been corrected, the article on the measurement of water revised and enlarged, and a new article added on sewage irrigation." The most important change in the revision consists in the addition of a new chapter on the use of water in foreign countries, including irrigation in Italy, Spain, France, Russia, Egypt, South Africa, India, Java, Japan, the Philippine Islands, Australia, western Canada, the Hawaiian Islands, Argentina, northern Brazil, Colombia, Peru, and Siam.

The article on sewage irrigation deals with experience, especially in southern California. In one case at Redlands "the sewage is conducted through the farm lands in underground sewer pipe and delivered to the fields through a modern hydrant system. The soil is a light sandy loam, naturally well drained, but not extremely absorbent. The principal crop irrigated is orange trees, which receive from 3 to 6 in. of sewage at intervals of 30 days, with the exception of the dormant season when the sewage is used on barley and oat land for its fertilizing value. Furrow irrigation is the only system of application used on all crops, and cultivation follows as closely as possible after irrigation. . . . The success of the Redlands disposal is principally due to the efficient system of distribution, the farm management of the sewage used, the very favorable natural conditions, and sufficient land."

In another case at Santa Ana "the raw sewage is distributed through a system of concrete pipe lines and valves to lands upon which sugar beets are grown. The soils vary from a heavy loam to a very light sandy loam. Two irrigations are used during the growth of a crop on the heavy lands, while as high as six are applied on the sandy lands during growth." Sterile sandy

lands have been built up with Santa Ana sewage by applications of approximately 8 in. every 30 days for two years before planting to sugar beets to maintain the fertility. It is estimated in this case that "sewage irrigation increases the yield of beets 3 to 4 tons per acre over clear-water irrigation....

"The sewage farm should be considered as a large receiving bed and a part of the purification system, upon portions of which the sewage is intermittently spread and where purifying takes place through the action of the soil bacteria and sunlight. For this reason an efficient distribution system on the farm is as important as any part of the plant. Every small stream of sewage should be under absolute control and a rotation of irrigation followed which will not overload any portion of the land and hinder the purification processes or the growth of crops. The bacteria dangerous to health may be destroyed by chemical treatment of the effluent from septic tanks, but this should not be necessary if proper precaution is taken to prevent the sewage getting into drinking water or coming into contact with vegetables which are to be eaten without cooking. . . .

"One of the chief causes of failure in sewage irrigation in the United States is the lack of proper irrigation construction and management on the farm. Open ditches still unfortunately prevail on sewage farms. These ditches are the greatest source of offensive odors due to the dangerous accumulations of putrefying matters which collect wherever there are weeds, pockets, or dead ends. Seepage from earthen ditches is apt to be large in porous soils and dangerous to the public health. The continuous control of sewage in ditches and an efficient division into irrigation units can best be obtained with a pipe and hydrant system. . . . The management of the sewage irrigated farm is a vital and serious problem upon which the success of the project depends."

Irrigation studies, Ontario and Covina [California], R. S. VAILE (Cal. Citrogr., 2 (1917), No. 5, pp. 9, 10, figs. 3).—Irrigation experiments with citrus orchards on comparatively open gravelly soil with a very pervious subsoil of coarse gravel at from 3 to 8 ft. are reported. The following conclusions were drawn as to economic methods of irrigation on these soils:

"Irrigation districts should be so far reorganized as to accommodate more frequent delivery of water to users. It is somewhat doubtful if more total water may be used to advantage provided the interval is reduced, although the data submitted does not entirely establish this point. Neither is it clear that 15 days is necessarily the correct interval. . . . Shorter furrows should be provided as rapidly as economic conditions justify."

It is further considered advisable to mulch the lower few rows of trees to prevent run-off and conserve moisture at that point.

Drainage as a correlative of irrigation, C. G. ELLIOTT (Trans. Internat. Engin. Cong., 1915, Waterways and Irrig., pp. 510-529, figs. 7).—It is the purpose of this paper to correlate the practices of irrigation and drainage "and, particularly, to show the methods of draining wet lands under irrigation as now successfully practiced in this country." Special attention is given to the work of the Drainage Investigations of the U. S. Department of Agriculture along this line, as formerly conducted under the supervision of the author.

Flood control for Pecatonica River (Ill. Rivers and Lakes Com. Bul. 18 (1916), pp. 33, pls. 2, flgs. 22).—This bulletin is compiled from the results of investigations made by the Illinois Rivers and Lakes Commission and the U. S. Geological Survey into the flood conditions of the Pecatonica Valley.

It is concluded "that the river, in its natural state, spreads out over the whole valley during flood periods, and the tendency is toward a general increase of flood height and property damage due to the silting up of the channel

and the encroachments of civilization. The benefits to be derived from a general project designed to prevent the inundation of the bottom lands of the valley as a whole would not, at the present time, be commensurate with the cost of such work, but the annual damage sustained at Freeport and vicinity is sufficient to warrant the outlay necessary to protect that city against a flood flow of 21,000 cu. ft. per second, or nearly 25 per cent greater than that of March 28, 1916. This protection can best be accomplished by providing channel area sufficient to carry a flood of 21,000 cu. ft. per second with a slope of approximately 0.5 ft. per mile . . . and where necessary constructing levees to protect the low sections against overflow. The required cross section can be most economically obtained by constructing an auxiliary channel."

Tests indicate drain tile beddings increase strength (Engin. Rec., 75 (1917), No. 12, pp. 459, 460).—This is an abstract of a paper presented by W. J. Schlick before the American Concrete Pipe Association, in which tests made at the Iowa Engineering Experiment Station are reported. These consisted of bedding 24-in. drain and sewer tile in shallow trenches and then loading them through a standard upper sand bedding. It was found that an increase in strength of 25 per cent may be obtained by careful earth bedding and as much as 90 per cent by certain forms of concrete bedding, especially in solid soils.

Report of hydrometric surveys (stream measurements), 1915, F. H. PETERS, P. M. SAUDER, ET AL. (Dept. Int. Canada, Irrig. Branch Rpt. Hydromet. Surveys, 1915, pp. V+590, pls. 13, flgs. 10).—This report presents the results of measurements of flow made on streams, irrigation ditches, and canals in Alberta and Saskatchewan during 1915.

Water supply, W. P. Mason (New York: John Wiley & Sons, 1916, 4. ed., rev., pp. X+528. pl. 1, figs. 129; rev. in Engin. News, 76 (1916), No. 25, p. 1181; Amer. Jour. Pub. Health, 7 (1917), No. 2, p. 197).—This book contains chapters on drinking water and disease; artificial purification of water; natural purification of water; rain, ice, and snow; river and stream water; stored water; ground water; deep-seated water; quantity of per capita daily supply; and action of water upon metals. Appendixes are included on analyses of sea waters, rights and duties regarding the pollution of streams, and typhoid fever contracted from drinking polluted water decided to be "an accident."

In the chapter on drinking water, considerable space is devoted to the distribution of typhoid fever and factors operating in its transmission. Newly developed methods of water purification, particularly processes aiming at disinfection, are considered, as are also certain recently discovered factors influencing natural purification in streams and stored waters. The use of chlorin, ozone, ultra-violet light, and copper sulphate receive a good deal of attention, and considerable space is also devoted to a discussion of various phases of the pollution of drinking water supplies and the care of watersheds.

Makawao waterworks for rural supply, J. B. Cox (*Engin. News*, 77 (1917), No. 8, pp. 310-312, figs. 2).—This is a description of a county water supply for a rural district in Hawaii, which is maintained under tropical conditions.

A simple method of water analysis, J. C. Thresh (London: J. & A. Churchill, 1915, 8. ed., pp. 69).—This book describes methods and equipment necessary for simple chemical analysis of water and describes the chlorin method of water purification, especially for residential or camp supplies.

Direct microscopical counting of bacteria in water, B. E. Nelson (Jour. Amer. Chem. Soc., 39 (1917), No. 3, pp. 515-523, fig. 1).—Experiments are reported, from which it is concluded that "direct microscopical counts of bac-

teria in water may be made in from 20 to 40 minutes and allow of the examination of other microorganisms at the same time."

It was found that "these counts are fully more accurate than those by the plate method, although not directly comparable with them. The centrifugal method of concentrating the bacteria after 'flocking' is the most rapid, but is less efficient and accurate than filtration. The morphological character of the organisms themselves, rather than the appearance of their growth, is considered in judging their possible general characteristics. These total counts are in no sense intended to supersede the specific cultural and other tests for *Bacillus coli* or other individual groups of organisms."

Bile compared with lactose bouillon for determining the presence of Bacillus coli in water, Maud M. Obst (Jour. Bact., 1 (1916), No. 1, pp. 73-79).— Experiments are reported in which it was found that lactose bouillon used as a substitute for lactose peptone ox-bile permitted the development of about twice as many B. coli from 191 samples of water as the bile medium.

"The bile was never used later than a week after collection. It was sterilized upon receipt and stored during this period at a temperature of 1° C. It was enriched with 1 per cent lactose and 1 per cent peptone and tubed in Dunham tubes. The lactose bouillon was made from neutral nutrient broth prepared with 0.5 per cent Liebig's meat extract, 1 per cent peptone, and 1 per cent lactose. . . .

"Lactose bouillon cost less in money and labor. The difficulty of obtaining pure, fresh bile puts it almost out of the reach of many workers. The stored bile proved to show progressive deterioration. Lactose bouillon can be prepared when desired and can be made more uniform. It need contain no precipitate to clog the inner tube or to affect the activity of the organism."

Septic tank, L. C. Hart and G. C. Jones (Ga. State Col. Agr. Circ. 41 (1917), pp. 7, figs. 5).—This circular briefly describes and ilustrates a septic tank made of 24-in. terra cotta pipe. A tile absorption area for final disposal is recommended.

Report of the joint committee on Federal aid in the construction of post roads (U. S. House Representatives, 63. Cong., 3. Sess., Doc. 1510 (1915), pp. 317, pls. 3).—This is the first report of the joint committee on Federal aid in the construction of post roads. It contains the following chapters:

Importance of good roads and Federal aid; desirability of congressional control; review of committee's work; data from foreign countries; data from the several States; tonnage transported over rural roads; rural free delivery roads; special transportation rates on material for road improvement; comparative statistics bearing upon Federal aid apportionment; statistics of wealth, debt, highway expenditures, etc.; comparative statistics on cost of road construction; the old Cumberland Road; instruction in highway and bridge engineering; synopsis of good-roads bills introduced in the Sixty-third Congress; and record on congressional action.

Two final chapters give a table showing comparative statistics on road systems of foreign countries and a bibliography. A financial statement is appended.

Highway traffic analysis and traffic census procedure, W. H. Connell (West. Engin., 8 (1917), No. 3, pp. 96-102, figs. 4).—This article outlines the procedure in the collection, classification, analysis, and application of traffic census data in their relations to the planning of a highway, the design and maintenance of pavements, the cleaning of highways, and traffic regulations.

A standard of carbureter performance, O. C. Berry (Gas Engine, 19 (1917), No. 4, pp. 196-200, figs. 5).—Tests on the proper carburetion of petroleum fuels, conducted at Purdue University, are reported.

It is concluded that "a wide range of mixtures of gasoline vapor and air can be used in an engine to give regular firing in all of the cylinders. At half-load and mid-speed on an automobile engine any mixture between 0.055 and 0.155 lb. of gasoline per pound of dry air can be fired, and practically full power will be developed between the limits of 0.065 and 0.115 lb. The highest power will be developed with a mixture of about 0.08, while the best efficiency will accompany the theoretically perfect mixture of 0.0671 lb.

"A change of engine speed apparently does not affect the mixture at which the best power or the best efficiency will be realized, or the ability of the engine to use the leaner mixture, but at the higher speeds a smaller amount of excess gasoline can be used successfully. A change of load does not noticeably affect the points of highest power or efficiency, but at the higher loads a wider range of extreme mixtures can be used. The engine can run idle with as wide a range of mixtures as it can when pulling a good load."

Rural electric service profitable in Wisconsin (*Elect. World*, 69 (1917), No. 12, pp. 565, 566).—This is an abstract of a report by F. C. Babson before the Wisconsin Electrical Association, in which the findings and opinions of the 1916 committee on rural electrical service were summarized as follows:

"(1) The construction of purely rural-service lines is not ordinarily warranted unless the saturation of service is such that a reasonable return on the added investment and sale of energy may be shown. (2) Rural-service consumers on transmission lines of not over 6,600 volts connecting towns or villages are ordinarily profitable if a suitable minimum charge is made. (3) A suitable minimum charge to cover the higher cost of service for rural consumers should be made, variously estimated at from \$2 to \$3 per month. (4) A low second step in the energy rate should be provided so as to encourage a sufficient use of the service by the farmer to make it practical and attractive."

Wet weather dryers for hay, H. HITIER (Jour. Agr. Prat., n. ser., 29 (1916), No. 17, pp. 289, 290, fig. 1).—A device is described and illustrated to be used as a framework upon which to stack hay in damp weather so that it will dry properly.

#### RURAL ECONOMICS.

The economic history of American agriculture as a field for study, L. B. Schmidt (Miss. Valley Hist. Rev., 3 (1916), No. 1, pp. 39-49).—The author points out that this phase of history has not hitherto received the attention at the hands of historians which its importance merits. He has attempted to define the economic history of agriculture as a field for study and to review some of the reasons why special attention should be directed to this field, and suggests some of the more important problems which this field offers for investigation.

Control factors in agricultural development, J. A. Bonsteel (Univ. Cal. Jour. Agr., 4 (1917), No. 6, pp. 183, 184, 201).—The author has classified the different factors influencing agricultural production under the head of climate, soil, markets, and human efficiency. He points out that the first two factors are reasonably constant and unchangeable while the other two are purely artificial and change rapidly. He points out some of the adjustments which are necessary in farming for it to keep up with changes in the marketing conditions and in the efficiency of the farming population.

Country planning, E. A. WAUGH (Amer. Civic Assoc. [Pub.], 2. ser., No. 8 (1916), pp. 13).—The author points out some of the problems to be solved in country planning, as well as methods of meeting them and organizing the rural communities. He also outlines the purposes, problems, and methods in detail.

The Torrens Land Transfer Act of Nebraska, T. A. Browne (Nebr. [Univ.] Hist. and Polit. Sci. Ser. Bul. 10 (1916), pp. 60, pl. 1, figs. 5).—The bulletin gives a brief historical sketch and detailed description of the Nebraska Torrens law, and arguments for and against the system as a permanent provision. The author also calls attention to the provisions of the Torrens law in the different States and compares it with other systems of land transfer. A bibliography is appended.

The Land-Title Registration Act of the State of New York (Albany, N. Y.: State, 1916, 2. ed., pp. 87).—This booklet gives, in convenient form, the land title registration statutes of New York, and a statement of the aim and methods of the Torrens system as adopted and available to landowners in New York State. The complete text of the statutes is included, as well as an introduction by D. Viele and J. C. Beacher.

Land settlement in California (Trans. Commonwealth Club Cal., 11 (1916), No. 8, pp. 369-465).—In this report are included papers by F. Adams on land settlement, by E. Mead on colonization in California, by R. L. Adams on financial considerations of California agriculture, and by E. E. Cox on farm tenantry in California. These papers are accompanied by a discussion.

Report of the commission on land colonization and rural credits of the State of California (Sacramento, Cal.: State, 1916, pp. 87).—This report contains a discussion of land colonization conditions in California, the methods of land settlement enterprises, the condition of settlers in colonies recently established, and the problem of tenantry and farm labor, together with a discussion of the methods and policy of land colonization in other countries.

The commission advises that there should be State supervision of settlement, to provide that adequate attention be given to water supplies and drainage in irrigated areas, that the land be suited for the purpose for which it is being sold, and that there be no misrepresentation in the advertising. It is also suggested that from 20 to 30 years be allowed to pay for the land, and that, after the initial payment, no further payments on principal be required for the first two years. The contract should, however, stipulate the character of the improvements which must be made. It also recommends that the payments on the land be on the amortization system and the amount of annual or semiannual payments be equal throughout the entire period.

Minutes of evidence taken before the departmental committee appointed by the president of the Board of Agriculture and Fisheries to consider the settlement and employment on the land in England and Wales of discharged sailors and soldiers (Dept. Com. Land Settlement Sailors and Soldiers [London], Minutes of Evidence, 1916, pp. IV+399).—The minutes of evidence discussed in the report previously noted (E. S. R., 36, p. 290).

Agricultural Argentina, J. R. PICKELL (Chicago: J. Rosenbaum Grain Co., [1917], pp. 124, figs. 50).—The author has set forth his observations of the people, methods of producing and distributing agricultural products, and rural, housing conditions.

[Farming and farm labor conditions in North Carolina] (Ann. Rpt. Dept. Labor and Print. N. C., 30 (1916), pp. 16-29).—These pages continue the data previously noted (E. S. R., 35, p. 589), adding data for 1916.

Amount and cost of labor required for growing crops in West Virginia, O. M. Johnson and A. J. Dadisman (West Virginia Sta. Bul. 163 (1916), pp. 3-11, fig. 1).—The data upon which this study is based was obtained by visiting farmers in 12 counties in different parts of West Virginia. From 15 to 30 records on each crop were taken in each county. The amount and cost of labor have been summarized as follows:

# Amount and cost of labor in growing crops in West Virginia.

Kind o crop.	Yield per acre.	Man days.	Horse days.	Total cost.
Corn. Wheat	18.4 bushels	5. 71 2. 31	4. 29 3. 36	\$12. 86 6. 83
Oats Hay Potatoes	1. 27 tons 154,6 bushels	2. 29 . 81 10. 17	2, 84 . 71 8, 24	6, 28 1, 91 23, 49
Buckwheat		2. 91 37. 76	2. 98 5. 31	7. 3- 61. 9

With the exception of hay the cost refers to the expense of growing and harvesting. In the case of hay it refers simply to the expense of harvesting. The man labor has been valued at 15 cts, per hour and horse labor at 10 cts, per hour for ten-hour days.

Women agricultural workers in Germany (Dept. Agr. and Tech. Instr. Ircland Jour., 17 (1917), No. 2, pp. 225-241).—This article describes the extent of the employment of women in agriculture, the type of farm work performed, social conditions among women agricultural workers, wages, and special education and organizations for their benefit.

Second annual report of the cooperative organization branch, 1915–16, W. W. Thomson (Saskatchewan Dept. Agr., Ann. Rpt. Coop. Organ. Branch, 2 (1915–16), pp. 30).—This report gives, for the Province of Saskatchewan, a list of the cooperative organizations, together with the extent of their business; also a brief description of the special accomplishments of the various types of associations during the year.

Monthly crop report (U. S. Dept. Agr., Mo. Crop Rpt., 3 (1917), No. 4, pp. 29-36, fig. 1).—This number contains the usual data regarding the estimated value of important products and the range of products at important markets. Data are also given concerning the condition of farm animals on April 1 and the estimated loss during the year, the condition of winter wheat and rye, and the preliminary estimates on the early cabbage, strawberry, and potato crops. There are likewise special reports on the portion of the total corn crop that is of marketable quality, the estimated value per acre of farm lands with and without improvements, the apple production and value by varieties, number of gas tractors in commission on farms, and a comparison of the increase in population, the production of 12 of the leading crops, the per capita production, and other data.

Ohio agricultural statistics, 1915-16 (Ohio Agr. Statis., 1915-16, pp. 75).— This report continues the information previously noted (E. S. R., 35, p. 497).

[Agricultural statistics for the United Kingdom, 1901-1915] (Statis. Abs. United Kingdom, 1901-1915, pp. 308-321).—These pages continue the information previously noted (E. S. R., 34, p. 792).

[Agricultural statistics of Spain] (Bol. Agr. Téc. y Econ., 9 (1917), No. 97, pp. 24-43).—These pages contain data showing by minor geographic divisions the production of principal crops for 1916, with comparative data for earlier years.

[Agriculture and live stock in Sweden] (Sveriges Off. Statis., Jordbr. och Boskapsskötsel, 1914, pp. IV+38; 1915, pp. IV+38).—These reports continue the information previously noted (E. S. R., 37, p. 93).

[Agricultural statistics of Java and Madura] (Jaarc. Konink. Nederlanden, Koleniën, 1914, pp. 70-82).—This report continues the data previously noted (E. S. R., 36, p. 594) adding data for 1914.

## AGRICULTURAL EDUCATION.

[Agricultural and home economics instruction] (Nat. Soc. Prom. Indus. Ed. Bul. 22 (1916), pp. 173-195, 212-225, 271-277, 291-324).—The following papers, presented at the 1916 meeting of the National Society for the Promotion of Industrial Education, are included: Home Economics Training as Related to Vocational Work, by Abby Marlatt and Lilla Frich, respectively; Vocational Significance of Domestic Art in the Schools, by Carrie L. Wilkerson; The Training of the Teacher of Household Arts for the Vocational School, by Anna M. Cooley; Business of Home-Making, by Mrs. Harvey M. Hickok; Significance of the Survey to the Vocational Training of Girls in Minneapolis, by Elizabeth Fish; Shop Methods and the Utilization of Product [at the Manhattan Trade School for Girls], by Violet Coen; Trade Extension and Part-time Courses for Girls in New York City, by Florence M. Marshall; Provision for Commercial Experience During the Period of Training [by the Womens' Educational and Industrial Union, Boston], by Antoinette Roof; Apprentice Teacher Training [in Agriculture], by G. A. Works; The Status of Teacher-Training for Agriculture in the United States, by A. C. Monahan; The Home Project as the Center v, the Home Project as the Outgrowth of Agricultural Instruction, by C. G. Selvig, previously noted (E. S. R., 35, p. 298); and Plans and Records of Home Project Instruction, by L. S. Hawkins.

Agriculture and the public schools, L. H. Dennis (Ann. Rpt. Penn. Dept. Agr., 21 (1915), pp. 249-263).—This is an illustrated lecture, in which the author discusses the problem of the agricultural leader and the three different types of secondary schools of agriculture, viz, the congressional district and the county agricultural schools and the agricultural department in an existing high school. He finds that the advantages of the latter are chiefly that it is near to the homes of the pupils, and it is not necessary to purchase and operate a school farm. The school farm is objected to mainly because it is very apt to be run under conditions that are not natural, so that the experience gained on such a farm does not always compare favorably with that gained in home-project work. "Descriptive notes are given on work at individual schools in explanation of lantern slides shown.

Vocational secondary education (U. S. Bur. Ed. Bul. 21 (1916), pp. 163).—
This report was prepared by the committee on vocational education of the National Education Association with the object of assisting the average superintendent of schools in a community of ordinary size in introducing such work, where needed, into his home school system. The report deals with the history and development, definitions, analysis, and illustrative examples of vocational secondary education, including agricultural and home economics education, types of vocational secondary schools, some ways in which vocational education may be introduced, methods of organization, proper methods of financing, problems, etc. A digest of laws of States that provide State aid for a more or less State-wide system of education is appended.

Vocational agricultural education, L. H. Dennis (Ann. Rpt. Penn. Dept. Agr., 21 (1915), pp. 429-443).—Notes accompanying an illustrated lecture to show what Pennsylvania is doing along the lines of vocational education in the secondary schools of the rural districts are presented.

A special report to the board of visitors of the Virginia Military Institute on the history of agricultural education in Virginia and the Virginia Military Institute as a school of agriculture, including a sketch of the physical survey of Virginia by the School of Applied Science, J. C. Wise ([Lexington], Va.: Author, 1914, pp. 34).—The author reviews the history of agricultural

education in Virginia, including an account of the establishment and development of agricultural instruction at the Virginia Military Institute, at Lexington, followed by the founding of the Hampton Normal and Agricultural School for colored students and the Virginia Agricultural and Mechanical College at Blacksburg.

The district agricultural schools of Georgia, C. H. Lane and D. J. Crosby (U. S. Bur. Ed. Bul. 44 (1916), pp. 32).—The authors give a brief history of the establishment of the district agricultural schools of Georgia, detailed descriptions of (1) the school plant and equipment of a typical school, with brief notes on special features of the other schools, and (2) the course in agriculture and domestic science. Statistical data with reference to enrollment of students, farms, farm crops, and animals of the various schools, a financial statement for 1911–12, and the text of the act creating the schools are appended.

Seventh annual report of the eleven district agricultural schools of Georgia, J. S. Stewart (Bul. Ga. State Col. Agr., No. 109 (1916), pp. 36).—This bulletin contains the minutes of the fifth annual meeting of the principals of the district agricultural schools, held April 28, 1916, the organization lists of the schools, reports of improvements and special features for the year at each school, the new curriculum adopted in May, 1915, the revised course of study for 1916–17, a suggested daily schedule, an account of the first Georgia District Agricultural School Contest, held at the Georgia State College of Agriculture April 28 and 29, 1916, the text of the act creating the schools, and statistical data on the value of farm products, repairs, salaries, value of the plant, attendance, farm acreages, and equipment.

The State appropriation for each of these schools for 1916-17 was \$15,000, an increase of \$5,000 over previous appropriations. Arrangements had been made with the college of agriculture to place a county agent or congressional district agent at each of these schools. Seven of the schools had teacher training departments, and the others reported that they would introduce such courses in September, 1916.

Ninth annual report of the inspector of high schools, E. R. EDWARDS (Ann. Rpt. Insp. State High Schools [N. Dak.], 9 (1916), pp. 75, pls. 5).—This report includes, among other information, statistical data on the enrollment, equipment, salaries of instructors, etc., with reference to agriculture and domestic science and art in North Dakota schools.

The agricultural enrollment in the high schools nearly doubled since the previous year, yet included only 16.2 per cent of the total enrollment. There were 1,420 students taking at least one unit of agricultural work as against 689 in 1914–15; 7 schools gave 2 units and 3 each gave 3 and 4 units. The 2 county agricultural and training schools had an enrollment of 110 and 24, respectively. The 5 State high schools with agricultural departments had a total enrollment of 176 in agriculture as against 133 in the previous year, and 118 in cooking and 151 in sewing.

Special equipment for instruction in agriculture was reported by 55 high schools. Of the first-class schools one reported such equipment valued at \$5,500 and another at \$500. The 5 schools with agricultural departments have an average agricultural equipment of \$830 each, and the other 48 schools an average of \$47.52.

List of agricultural and horticultural officials, institutions, and associations (Dept. Landb., Nijv. en Handel [Netherlands], Verslag. en Meded. Dir. Landb., No. 2 (1916), pp. 128).—This is the official organization list of the Direction of Agriculture of the Department of Agriculture, Industry, and Commerce, including higher and secondary agricultural education and research

institutions, agricultural and horticultural winter schools and courses, itinerant instructors, and associations in the Netherlands in 1916.

High-school courses in Agriculture, S. H. Dadisman and G. M. Wilson (Iowa State Col., Schools Circ. 5 (1916), pp. 56).—This bulletin outlines a four-year course in agriculture for high schools comprising instruction in farm animals for one year, in farm crops, horticulture, poultry, and farm management one-half year each, in farm mechanics two-fifths of a year, and in soils three-fifths of a year. A suggestive schedule for one, two, three, and four year courses, laboratory and field exercises and home products, and references to helpful literature are included. It is stated that the outlines have been prepared to assist the high-school teachers of Iowa in organizing agricultural instruction on a thoroughly practical basis.

Illustrated lecture on leguminous forage crops for the South, C. V. PIPER and H. B. HENDRICK (U. S. Dept. Agr., States Relat. Serv. Syllabus 24 (1917), pp. 16).—The authors discuss the distinguishing characteristics of the leguminous plants, the function of root nodules and nodule bacteria, inoculation, the relation of legumes to cropping systems, commendable cropping systems, the utilization of leguminous crops, legumes as green manures, and the principal leguminous crops for the South. A list of fifty lantern slides to illustrate the syllabus is appended.

Illustrated lecture on leguminous forage crops for the North, C. V. PIPER and H. B. HENDRICK (U. S. Dept. Agr., States Rel. Serv. Syllabus 25 (1917), pp. 18).—This syllabus corresponds in treatment to that for the South, noted above, but deals with the principal leguminous crops for the North. A list of 45 lantern slides to illustrate the lecture is appended.

Types and market classes of live stock, H. W. Vaughan (Columbus, Ohio: R. G. Adams and Co., 1916, pp. 448, pl. 1, figs. 117).—This text consists of a study of the types, carcasses, breeding for market and other purposes, markets, and products of cattle, sheep, swine, and horses. The arrangement of the subject matter corresponds to the order usually followed in teaching, but may be varied, as the study of each class of animals is complete in itself. A loose-leaf edition of the text has been used at the beginning of the work in animal husbandry at the Ohio State University during the past three years.

[Nature study and elementary agriculture in Georgia] (In Manual Ga. Teachers, 1916, pp. 168-202, figs. 3).—This manual includes the following articles: (1) Nature Study and Agriculture, by R. J. H. DeLoach, which discusses the objects and results of nature study and its relation to agriculture, and the true conception of agriculture as a subject to be taught in the common schools, and outlines practical lessons in nature study; (2) School Clubs, by M. L. Duggan and supervisors, giving directions for the organization and work of boys' and girls' clubs; and (3) Easy Experiments in Agriculture.

Class projects for agriculture students, W. S. Welles (River Falls, Wis.: State Normal School, 1916, pp. 19).—Class projects are outlined in weeds and seed inspection, marketing, agricultural pedagogy, economic entomology, agricultural biology, feeds and feeding, field crops, farm management, dairying, farm mechanics, soils, and animal husbandry.

Home projects in agriculture for Michigan high schools and school credits, W. H. French (Mich. Agr. Col., Dept. Agr. Ed. Bul. 17 (1916), pp. 15, fig. 1).—The author discusses suitable home projects for students in agriculture in public high schools and offers suggestions and recommendations with reference to proper school credit for such project work.

Practical arts below the seventh grade ([Indianapolis]: State Supt. Pub. Instr., 1916-17, pp. 35).—This is an outline in agriculture, domestic science,

and industrial arts, including suggestions for practical work and correlation with other school subjects, for the first six grades of the Indiana public schools. A suggestive list of books for reference in practical arts work is included.

#### MISCELLANEOUS.

Report of Hawaii Station, 1916 (Hawaii Sta. Rpt. 1916, pp. 46. pls. 6).—This contains the organization list, a summary by the agronomist in charge as to the work of the year, and reports of the divisions of horticulture, chemistry, plant pathology, agronomy, extension, and Territorial marketing, and of the Glenwood substation. The experimental work recorded is for the most part abstracted elsewhere in this issue.

Annual Report of South Dakota Station, 1916 (South Dakota Sta. Rpt. 1916, pp. 27).—This contains a report by the director on the organization, work, and publications of the station, a financial statement for the fiscal year ended June 30, 1916, and departmental reports, of which a portion of that of the horticulturist is abstracted on page 142 of this issue.

First Annual Report of the Adams Branch Experiment Station, 1916, M. A. M'Call (Washington Sta. Bul. 138, pp. 16, figs. 9).—This contains a report of the superintendent of this substation for the fiscal year ended June 30, 1916, including a description of the projects initiated.

Monthly Bulletin of the Ohio Agricultural Experiment Station (Mo. Bul. Ohio Sta., 2 (1917), Nos. 1, pp. 34, figs. 5; 2, pp. 37-68, figs. 10; 3, pp. 71-102, figs. 6).—These numbers contain, in addition to several articles abstracted elsewhere in this issue and miscellaneous notes, the following:

No. 1.—The Wheatfield in Winter.—Improvement by Use of Manure, Commercial Fertilizers and Lime, by C. E. Thorne; Corn and Oats for Work Horses.—A Comparison of Their Efficiency and Economy in Feeding, by B. E. Carmichael, adapted from Bulletin 195 (E. S. R., 20, p. 470); The Field Bean.—A Promising Crop for Many Ohio Farms, by S. N. Green; White Snakeroot a Poisonous Plant.—Trembles in Animals and Milk Sickness in Man Often Fatal, by A. D. Selby; Composition of Limestone.—The Relative Merits of Magnesian and Nonmagnesian Forms, by J. W. Ames and C. J. Schollenberger, an extract from Bulletin 306 (abstracted on page 124); Selling Woodlot Products.—Advantages Secured through Cooperative Marketing, by J. W. Calland, an extract from Bulletin 302 (E. S. R., 36, p. 244); The Feeding Situation.—Suggestions for Computing Winter Rations for Dairy Cows, by C. C. Hayden; and Farm-management Field Studies.—A Reconnaissance Conducted in Butler Township, Knox County, by C. W. Montgomery.

No. 2.—Mineral Requirements of Milch Cows.—Heavy Milk Production Involves Loss of Minerals from Body, by E. B. Forbes, an abstract of Bulletin 308, noted on page 169; Boys' and Girls' Club Work.—County-agent Demonstration in Butler Township, Knox County, by C. W. Montgomery.

No. 3.—Range Versus Confinement for Laying Hens.—Profits Materially Increased under Range Conditions, by W. J. Buss, an abstract of a portion of Bulletin 291 (E. S. R., 35, p. 171); Fire Blight.—Timely Suggestions for Its Control, by R. C. Walton; Cutworms.—Their Habits, Characteristics, and Means of Control, by H. A. Gossard; and Arlington Timothy.—New Variety Being Sent from Experiment Station.

#### NOTES.

Connecticut State Station.—The general assembly has appropriated \$28,000 for the construction of a central heating plant and added \$2,500 per year to the maintenance appropriation of the station. Other appropriations for the biennium include \$12,000 for the State entomologist, \$40,000 for the suppression of gipsy and brown-tail moths and nursery inspection, \$1,500 for bee diseases, \$10,000 for the elimination of mosquito breeding, \$15,000 for the control of white pine blister rust, \$5,000 for the State forester, \$5,000 for the purchase of forest land, and \$9,000 for the fire-warden service.

Florida Station.—Recent appointments effective July 1 include Miss Mildred Nothnagel, Ph. D., as assistant plant physiologist, Arthur M. Smith as assistant chemist, and C. W. Long as laboratory assistant in animal husbandry.

Hawaii College.—D. L. Crawford, of Pomona College, has been appointed professor of entomology beginning in September.

Purdue University and Station.—O. F. Hunziker, chief of the dairy department, who has been on leave of absence for a year to study commercial butter making, has resigned to continue in commercial work.

Iowa College.—Paul R. Lisher, associate professor of animal husbandry, has resigned to become county adviser for the Will County (Illinois) Farm Bureau.

Kansas College and Station.—The station, assisted by the Office of Cereal Investigations, U. S. Department of Agriculture, has made a complete survey of Kansas to determine the location of pure seed of the hard red winter varieties of wheat. A circular giving the names of the farmers and elevator men having the seed for sale is being prepared to place in the hands of farmers and organizations in counties where the entire wheat crop was winter killed and the seed will be needed.

The staff of the department of entomology and Federal entomologists are being organized to control the Hessian fly in counties where it promises to injure the wheat crop in 1918. The early and thorough plowing under of wheat stubble, elimination of volunteer wheat in fields later, and planting after the fly-free date are the recommendations being made. These practices, however, are advisable in order to obtain maximum yields, regardless of Hessian fly infestation.

Chas. A. Scott, professor of forestry, forester of the station, and State forester, has resigned to engage in commercial work. Ralph Kenney, assistant professor of crops, has resigned to accept a commercial position in Paraguay.

Dr. Geo. M. Potter, veterinary inspector of the Bureau of Animal Industry of the U. S. Department of Agriculture, has been appointed specialist in veterinary medicine in the extension division and entered upon his duties about May 1. His work deals especially with hog cholera and contagious abortion.

Appointments to fellowships in the division of agriculture for the ensuing year include Jay L. Lush of the Kansas College in animal genetics, Levi J. Horlacker of Purdue University in animal production, W. P. Tuttle of the Kentucky University in soils, and W. H. Stacy of the Iowa College in crops.

Louisiana Stations.—W. L. Owen, bacteriologist of the Sugar Station since 1908, has resigned effective October 1, to take charge of the research department of a large sirup and molasses canning industry in New Orleans.

Michigan College and Station.—Ezra Levin has been appointed muck crop specialist with headquarters at Kalamazoo. His time is to be divided between research and extension work.

Minnesota University and Station.—A chair of comparative pathology and bacteriology has been established in the veterinary division, to which Dr. Clifford P. Fitch, assistant professor of pathology and bacteriology in the New York State Veterinary College, has been appointed beginning August 1. Dr. Fitch will also become chairman of the veterinary division of the animal industry group, succeeding Dr. M. H. Reynolds, who will be in charge of veterinary sanitation.

Philip A. Anderson, instructor in animal husbandry, has been appointed in charge of a new section of meats in the animal industry group. Alice L. Edwards has been appointed assistant professor of nutrition beginning August 1.

John T. Stewart, chief of the division of agricultural engineering, has been granted leave of absence to accept a commission in the engineering corps of the U. S. Army. Louise Jensen has resigned as mycologist of the station and has been succeeded by F. Jean MacInnis of the Illinois Station. Phil C. Bing of the Wisconsin University and Station has succeeded L. G. Hood as assistant editor. Mildreth J. Haggard has resigned as assistant chemist in animal nutrition.

Nebraska University and Station.—The contract has been let for the agricultural engineering building at a cost of \$132,450.

The department of animal husbandry is experimenting with various crops for hog and sheep pastures. Rape, cane, sweet clover, and oats are being compared with the blue grass and alfalfa.

New Hampshire College.—Ralph D. Hetzel, director of the extension service of the Oregon College, has been appointed president beginning about August 15.

New Jersey College and Stations.—W. J. Carson, professor of dairy husbandry and dairy husbandman, L. S. Riford, instructor in dairy husbandry and assistant in the State Station, Thurlow C. Nelson, biologist in charge of oyster investigations, and Howard F. Huber, extension specialist in horticulture, have resigned. Wm. M. Regan has been appointed dairy husbandman, and Willes B. Combs, assistant dairy husbandman. Other appointments include J. T. Barlow as research assistant in plant physiology, Miss Jessie G. Fiske as assistant seed analyst, C. S. Clarkson as assistant chemist, D. A. Coleman, Ph. D., as assistant agronomist, and H. M. Biekart as florist.

New York State Station.—A. J. Flume, assistant chemist, has resigned to take up commercial work and is succeeded by Walter L. Kulp, formerly assistant in bacteriology at the Michigan College and recently engaged in bacteriological work in connection with hospitals in Boston, Mass.

Oregon College.—A bequest estimated at from \$25,000 to \$40,000 has been made to the college by the late J. T. Apperson, a member of the board of regents since its establishment, for use as a permanent loan fund to students working their way through college.

Pennsylvania College and Station.—Recent changes in title and promotions include the following: As professor, A. W. Cowell, landscape art; as associate professors, C. E. Myers, plant breeding, and C. F. Noll and J. W. White, experimental agronomy; as assistant professors. C. R. Anderson, forestry, S. I. Bechdel, dairy husbandry, J. R. Bechtel, vegetable gardening, A. F. Mason, horticultural extension, L. O. Overholts, Ph.D., botany, E. I. Wilde, floriculture, F. N. Fagan, pomology, and C. L. Goodling, farm management (and superintendent of farms); and as instructors, H. P. Cooper and D. C. Wimer, agronomy, L. P. McCann, animal husbandry, R. S. Spray, botany, J. S. Gardner, plant breeding, and L. D. Jesseman and A. F. Yeager, pomology. E. R. Hitchner has

resigned as instructor in bacteriology, effective July 1, and Paul Gerlaugh, as instructor in animal husbandry, effective August 1.

W. W. Farnham has been appointed instructor in landscape gardening, beginning March 19. Miss Etta J. McCoy, Miss Elsie Noble, Miss Edith Hershey, and Miss Jeanette Bliss have been appointed instructors in home economics extension, beginning June 25, and Miss Mary V. Dick. beginning July 1.

Tennessee University and Station.—A bond issue of \$1,000,000 has been authorized by the State legislature for buildings and other improvements, supplemented by the proceeds of a half mill tax, estimated to produce about \$336,000 per annum at present and to be used for maintenance. About \$100,000 may be used for the construction of buildings at a substation in middle Tennessee, to be located on land provided by the county securing the institution. Provision will also be made for a large central administration building, a building for the College of Agriculture, an auditorium, and other buildings.

As the result of unanticipated findings in the lysimeter studies on lime and magnesia, begun in July 1914, the problem of sulphur conservation is to be taken up. This involves an additional equipment of 22 lysimeter tanks of the hillside equipment type, previously described (E. S. R., 32, p. 719).

W. A. Holding has been appointed assistant chemist.

Utah Station.—An experimental dry farm to investigate problems of high altitude has been established at Widtsoe in Garfield County.

Tracy H. Abel, M. S., has been appointed assistant horticulturist, and A. O. Larson, B. S., assistant entomologist.

West Virginia University and Station.—The recent legislature granted an additional \$75,000 for the agricultural building, thus making it possible to complete the entire structure during the summer and fall, whereas otherwise an important segment would have been left uncompleted. The legislature also appropriated \$20,000 for buildings on the new farms, and made a small increase for operating expenses and a special emergency appropriation of \$10,000 to meet the abnormally high prices of apparatus, chemicals, etc.

Wisconsin University and Station.—Special exercises were held during Commencement in recognition of the twenty-fifth anniversary of the conferring of the Ph.D. degree upon Dean Russell and his completion of 24 years of service at the university. In connection with the occasion, a compilation of the published results of the bacteriological work carried on during this period, aggregating some 2,000 pages, was presented to him.

Wyoming University and Station.—Dr. C. A. Duniway has resigned as president to become president of Colorado College, Colorado Springs. Dean H. G. Knight was granted the degree of doctor of philosophy by the University of Illinois in June. T. S. Parsons, agronomist, has been given a year's leave of absence for graduate work at the University of Wisconsin. W. A. Albrecht has been appointed acting agronomist for the year, and Joe Robinson has been appointed assistant agronomist. P. T. Meyers has resigned to become county agent for Campbell County.

Federal Board for Vocational Education.—Nominations to complete the membership of this board were transmitted to the Senate by President Wilson on June 29. The nominees include Arthur E. Holder of Iowa as a representative of the labor interests for a term of three years, Charles A. Greathouse of Indiana as a representative of the agricultural interests for a term of two years, and James Phinney Munroe of Massachusetts as a representative of the manufacturing and commercial interests for a term of one year. These appointments were confirmed by the Senate July 17.

Agricultural and Home Economics Instruction in Utah.—An act of the 1917 legislature of Utah creates the positions of State supervisor of agricultural

and industrial education and State supervisor of home economics education for the high and district schools of the State. The State leader in junior vocational work at the Utah College is designated for the former position, and the State leader for junior vocational work for girls for the latter. Appointees to these positions must be 25 years of age or over, have at least a B. S. degree in agriculture or home economics, respectively, understand the practical side of agriculture and home economics, and possess the qualifications prescribed by the State board of education. The duties of these supervisors will be to systematize the teaching of agriculture, mechanic arts, and home economics in these schools, suggesting the courses particularly suited to the individual students and to the communities in which the schools are located and the best methods of teaching the principles underlying agricultural, industrial, and home economics work in the school room and laboratory, and the practical work to be done at home. They are to visit each county school district in the State at least once a year, and do their work under the supervision of the board of education and in cooperation with the Utah college and State normal school of the University of Utah. Their salaries will be paid by the college as leaders of vocational work.

The legislature also accepted the benefits of the Federal act for the promotion of vocational education. It designated the State Board of Education as the agency to cooperate with the Federal board in the administration of the provisions of the act, and the State treasurer as the custodian of the funds. An appropriation of \$12,500 was made for the biennium ending March 31, 1919.

Forest Ranger Course for the Southern Appalachians.—The Lincoln Memorial University at Harrogate, near Cumberland Gap. Tenn., has recently organized a department of forestry for the purpose of furnishing a training suitable to the needs of farmers and other owners of woodland, and which will equip boys as rangers in Government, State, and private employ.

The course will cover one year of 12 months, divided into four terms of three months each. Each term is made a unit in itself, and aims to give a definite knowledge about some one phase of the practical work. The course will include the elements of forestry (fundamental needs and purposes, the relation of forests to water resources, the effect of forest destruction, the benefits to the community in maintaining forests in a productive condition, etc.), forest botany, elementary field surveying, forest protection, timber cruising and mapping, logging and scaling, manufacturing and marketing of products, silviculture, forest improvements, and elementary land law.

The greater part of the instruction will be given in the forest or in connected nection with practical field problems. As a forest laboratory the university has secured a timber tract of 2,080 acres extending along the Cumberland Mountains from Cumberland Gap east into Virginia. This tract contains many thousand feet of merchantable timber, a large part of which is mature and will be cut as soon as possible.

Mobilizing Massachusetts Boys for Farm Labor.—A subcommittee of the Massachusetts public safety committee is endeavoring to mobilize the school boys of the State for farm service. It is planned that those under 16 years of age are to stay in their local communities and work on community or home gardens, while those 16 years or older are asked to enlist for farm work outside their own communities when needed.

A distinctive badge and certificates of honorary discharge are among the forms of recognition contemplated. Arrangements have also been made with the Massachusetts Agricultural and Tufts colleges, Boston University, and the Massachusetts Institute of Technology, whereby these institutions have agreed to accept for a trial period without entrance examination such boys as present

an honorary discharge from this service, had satisfactory school records at the time of leaving, and are recommended by their principals.

The existing school organization is being utilized, as far as possible, in conducting the enterprise and supplying the necessary supervision. Up to June 1, about 500 boys from 16 to 18 years of age had been released from high schools and State-aided vocational agricultural schools and departments for the work, while several hundred others were working while living at home or were to be released June 10. Nine camps for housing the boys had been established, with three others under way.

New Journals.—The experiment stations in the Netherlands Indies are issuing a journal, Archief voor de Rubbercultuur in Nederlandsch-Indië, the first number of which appeared in February, 1917. This journal is to include all of the stations' articles on rubber and will supersede the various bulletins and pamphlets previously publishing such articles. Although the articles will be written in Dutch, extensive abstracts or summaries in English treating all important points will be added. The committee of editors is composed of the directors and scientific officers of the experiment stations.

The Journal of Soil Improvement is being issued monthly as the official publication of the Wisconsin Soil Improvement Association. The initial number consists mainly of several short articles by members of the staff of the Wisconsin University and Station on various phases of soil improvement.

Madroño is being published at irregular intervals as the journal of the California Botanical Society. The initial numbers contain a number of original articles on various botanical phases.

Miscellaneous.—A grant of \$625,000 has been made from the Development Fund as a loan for the development of sugar beet growing and sugar manufacture in England. An estate of 5,600 acres has been acquired at Kelham, near Newark, where a factory will be erected. The enterprise is to be under the management of the British Sugar Beet Growers Society, Ltd., an organization not trading for profit, and an ultimate expenditure of \$2,500,000 is contemplated.

Following a suggestion from the Council of the Royal Horticultural Society, the University of London has established a degree of bachelor of science in horticulture. The university has also under consideration the recognition of the society's school and research station at Wisley as a school of the university.

Charles F. Baker, professor of agronomy in the University of the Philippines, has been granted a year's leave of absence to accept a temporary appointment as assistant director of the botanical gardens at Singapore, in charge of experimental work in tropical agronomy.

An act of the Wyoming State Legislature, approved February 1, 1917, provides for the establishment of normal training departments in the graded high schools of the State, and requires, among other subjects, the teaching of agriculture.

## EXPERIMENT STATION RECORD.

Vol. 37.

ABSTRACT NUMBER.

No.3.

#### RECENT WORK IN AGRICULTURAL SCIENCE.

#### AGRICULTURAL CHEMISTRY—AGROTECHNY.

The preparation of pure crystalline mannose and a study of its mutarotation, C. S. Hudson and H. L. Sawyer (Jour. Amer. Chem. Soc., 39 (1917), No. 3, pp. 470-478).—A method of crystallizing mannose directly and in large yield from the products of acid hydrolysis of vegetable ivory (the endosperm of the seed of the tagua palm, Phytelephas macrocarpa) has been devised and is described in detail. The rate of mutarotation of an aqueous solution was carefully studied, the results indicating that it is similar to that of other aldose and ketose sugars and is caused by a balanced reaction between a-mannose and  $\beta$ -mannose.

The acetyl derivatives of the sugars, C. S. Hudson (Jour. Indus. and Engin. Chem., 8 (1916), No. 4, pp. 380-382).—An address delivered at the presentation of the Nichols medal to the author, March 10, 1916.

A relation between the chemical constitution and the optical rotatory power of the phenylhydrazids of certain acids of the sugar group, C. S. Hubson (Jour. Amer. Chem. Soc., 39 (1917), No. 3, pp. 462-470).

The reactions of both the ions and the molecules of acids, bases, and salts; the inversion of menthone by sodium, potassium, and lithium ethylates, W. A. GEUSE and S. F. ACREE (Jour. Amer. Chem. Soc., 39 (1917), No. 3, pp. 376-388, figs. 3).

Concerning the failure to detect ornithin in plants, A. Kizel (Kiesel) (Izv. Imp. Akad. Nauk (Bul. Acad. Imp. Sci. Petrograd), 6. ser., 1915, No. 15, pp. 1661-1665).—The author considers previous failures to detect ornithin in plants to be due to the lack of proper conditions for successful analyses. Experiments were conducted with ornithin obtained from arginin from edestin of hempseed by the action of arginase from liver and from wheat sprouts. From the results of the experiments it is concluded that the following conditions are necessary for the best precipitation of ornithin by phosphotungstic acid: More concentrated solutions of ornithin; a large excess of phosphotungstic acid to reduce the solubility of the precipitated ornithin; increased acidity of the solution during precipitation; washing of the precipitate with phosphotungstic acid or a mixture of phosphotungstic and sulphuric acids, rather than with 5 per cent sulphuric acid alone; and allowing the precipitate to stand for some time before filtration, as the precipitate forms very slowly.

Decomposition of pyroracemic acid by dead plants in the presence of a hydrogen acceptor, V. I. Palladin, E. I. Lovchinovskaîa, and A. I. Aleksteev (Izv. Imp. Akad. Nauk (Bul. Acad. Imp. Sci. Petrograd), 6. ser., 1915, No. 7, pp. 589-600).—In earlier work the authors have studied the influence exerted by hydrogen acceptors on alcoholic fermentation and respiration of plants, as

well as on the decomposition of individual organic compounds in the course of these processes. Pyroracemic acid appeared among the decomposition products in both cases. In the work submitted the effect of the addition of methylene blue on the process of decomposition of pyroracemic acid resulting in the formation of acetaldehyde and carbon dioxid was determined.

In general, it is concluded that methylene blue retards the decomposition of potassium pyroracemate by old yeast and the sprouts of wheat, especially during the first hours of the reaction. A slight stimulation, however, was observed with pea seeds. The formation of acids takes place along with the activity of carboxylase. Methylene blue is considered to take up the hydrogen of water and thus favor the accumulation of acids through the remaining oxygen.

Activity of reductase and carboxylase in decomposition of lactic acid by yeasts, V. I. Palladin, D. A. Sabinin, and E. I. Lovchinovskafa (*Izv. Imp. Akad. Nauk (Bul. Acad. Imp. Sci Petrograd*), 6. ser., 1915, No. 8, pp. 701-718).—The results of the investigation reported are summarized as follows:

The decomposition of potassium lactate by dead yeast in the presence of methylene blue leads to a splitting off of carbon dioxid with the production of acetaldehyde. Theoretically, one-half of the carbon dioxid should be in the free state and the other combined as potassium carbonate, but in reality a much larger quantity of carbon dioxid is given off. If the decomposition of potassium lactate by dead yeast takes place in a current of air oxygen is energetically absorbed and the ratio  $\frac{\mathrm{CO}_2}{\mathrm{O}_2}$  approaches unity.

The decomposition of lactic acid by yeasts in the presence of a hydrogen acceptor consists of, first, the separation of hydrogen by reductase with the production of pyroracemic acid and, secondly, the splitting off of carbon dioxid from the pyroracemic acid through the action of carboxylase, with the production of acetaldehyde. Since pyroracemic acid is considered to be an intermediate product of alcoholic fermentation, its production from lactic acid is considered to offer new proof that lactic acid is an intermediate product of alcoholic fermentation.

Decomposition of lactic acid by killed yeast, V. I. Palladin (W. Palladin) and D. A. Sabinin (Izv. Imp. Akad. Nauk (Bul. Acad. Imp. Sci. Petrograd), 6. ser., 1916, No. 3, pp. 187-194; Biochem. Jour., 10 (1916), No. 2, pp. 183-196).—
The authors endeavored to determine under what conditions the decomposition of lactic acid would produce alcohol instead of acetaldehyde. Methylene blue as ordinarily used for a hydrogen receptor was replaced by pyroracemic acid which, when decomposed by carboxylase, yields acetaldehyde. The data submitted, while not considered to prove conclusively that lactic acid is the intermediate product of alcoholic fermentation, are indicated as showing that alcohol does not present the result of decomposition but the product of reduction of acetaldehyde by removing the hydrogen from one of the intermediate products of the decomposition of glucose.

Investigations on the significance of hydrogen in 'alcoholic fermentation and respiration have shown that on the reductions depend the anaerobic oxidations. During the formation of the intermediate products in the molecule of glucose the hydrogen and not the oxygen is displaced. The chemical processes of alcoholic fermentation and respiration can not be explained by reactions of decomposition alone, as the hydrogen is displaced not only within the confines of one molecule but also passes from one molecule into another. Points in favor of the theory that lactic acid is an intermediate product in alcoholic fermentation are discussed.

The effect of alcohol and methylene blue on the formation of carbon dioxid by dead yeast, V. I. Palladin and E. I. Lovchinovskaîa (*Izv. Imp. Akad. Nauk* (*Bul. Acad. Imp. Sci. Petrograd*), 6. ser., 1916, No. 4, pp. 253-256).—Experiments are reported, the purpose of which was to determine whether or not those plants which are able to oxidize alcohol upder normal conditions may do so in the presence of a hydrogen acceptor with the formation of carbon dioxid.

The results obtained in general were negative. Preparations containing alcohol and methylene blue sometimes produced slightly more carbon dioxid than mixtures with alcohol alone. This small increase is attributed to the stimulation of the process of fermentation by the methylene blue.

On reductase of plants, V. I. Palladin, P. G. Platishenskii, and E. V. Élladi (Izv. Imp. Akad. Nauk (Bul. Acad. Imp. Sci. Petrograd), 6. ser., 1915, No. 4, pp. 309-326, fig. 1).—It is indicated that the process of reduction in living organisms is of much more general occurrence than any other enzymic process, and that a thorough knowledge of its mode of action is especially important for the correct conception of the process of respiration. Experiments carried on with seeds and sprouts of peas, wheat sprouts, and several preparations of yeast are described in detail. The progress of reduction was determined by comparison with control solutions of methylene blue.

Soaking was found to accelerate reduction in pea seeds considerably. An acceleration was also noted in pea sprouts, especially on the addition of potassium bicarbonate. It is considered to be quite possible that germination is accompanied by an increase in the amount of reductase.

Extracted yeast reduced methylene blue less easily than nonextracted. The reductase activity was paralyzed by autolysis. Boiled taka-diastase was found to act as a coezym, while the unboiled exerted no influence. Peroxidase inhibited the action of reductase.

Water was found indispensable for the activity of the enzym, while glycerin, pyridin, alcohol, and formamid retarded its activity. Potassium hydroxid in moderate quantities greatly stimulated reduction, but in larger amounts retarded it. The action of calcium hydroxid was the reverse of that of potassium hydroxid, while magnesium oxid exerted a stimulative action. The presence of reductase in commercial diastase, taka-diastase, and emulsin was not determined with certainty.

It is indicated that the course of reduction depends on the amount of reductase and the substance to be oxidized, as well as on the amount of the hydrogen acceptor (substance to be reduced).

The action of peroxidase on chlorophyll, V. Løubienko (Izv. Imp. Akad. Nauk (Bul. Acad. Imp. Sci. Petrograd), 6. ser., 1915, No. 11, pp. 1159–1170).— The author notes a recently discovered enzym of green plants, provisionally named antioxidase, which paralyzes the oxidizing activity of peroxidase and thus protects chlorophyll from decomposition in the course of the process of assimilation. The action of the antioxidase ceases immediately on the addition of antiseptics which destroy the new enzym, and rapid decomposition of chlorophyll follows.

The effect of the reaction of the medium on the activity of inulase of Aspergillus niger, A. Kizel (Kiesel) (Izv. Imp. Akad. Nauk (Bul. Acad. Imp. Sci. Petrograd), 6. ser., 1915, No. 11, pp. 1077-1092, figs. 3).—The action of inulase extracted from the mycelium of A. niger on inulin obtained from dahlia roots was tested in the presence of sulphuric, hydrochloric, phosphoric, and acetic acids, sodium nitrate, disodium phosphate, disodium citrate, monosodium phosphate, and monosodium citrate.

A slight increase of the activity of inulase was noted in the presence of the acids, while a great activation was afforded by the acid salts, especially disodium citrate and monosodium phosphate. Alkaline salts, on the contrary, appeared to exert a harmful effect on the activity of the enzym.

Studies of arginase and urease in plants, A. Kizel (Kiesel) (Izv. Imp. Akad. Nauk (Bul. Acad. Imp. Sci. Petrograd), 6. ser., 1915, No. 13, pp. 1337-1364).—Confirming earlier findings the author ascertained the presence of arginase and urease in Aspergillus niger, and also established the occurrence of the enzyms in ergot on Secale cornutum, in vetch (Vicia sativa), and in ripe fruits of Angelica silvestris, as well as the presence of urease in etiolated sprouts of the white lupine. In previous work the existence of arginase in the sprouts of the white lupine and both arginase and urease in meadow mushrooms had been established.

The enzyms of A. niger were found not to split guanidin tetramethylenamin, although there was a partial cleavage of tetramethylendiguanidin with the formation of guanidin tetramethylenamin. The enzyms found in ergot, meadow mushrooms, and vetch do not decompose either of these reagents. In the work with the enzyms of the ergot, guanidin also remained unchanged. In some experiments with the white lupine and red clover (Trifolium pratense), in which only tetramethylendiguanidin was used, no cleavage of the reagent was observed.

The experimental procedures used and the data obtained are described in detail.

Effect of medium on proteolytic enzyms of plants, V. I. Palladin (*Izv. Imp. Akad. Nauk* (*Bul. Acad. Imp. Sci. Petrograd*), 6. ser., 1916, No. 7, pp. 527-538).—Since proteolytic enzyms affect the activity of other enzyms, particularly the oxidases, the author attempted to determine experimentally substances which would check the action of the proteolytic enzyms but would not at the same time be harmful to the oxidative enzyms. Preparations of yeast and wheat sprouts served as experimental material, and sucrose, glycerin, ethylenglycol, pyroracemic acid, formalin, and sodium chlorid were tested as inhibitors.

Corroborative evidence was obtained in regard to the poisonous action of formalin on the proteolytic enzyms of yeast. A 1 per cent solution of pyroracemic acid neutralized by potassium hydroxid exerted practically no influence. The other substances were found to divide themselves into two groups, electrolytes and nonelectrolytes. Nonelectrolytes retarded the action of proteolytic enzyms in a manner proportionate to their concentration, while weak solutions of the electrolytes stimulated the action of proteolytic enzyms. A strong solution of sodium chlorid slightly inhibited the action, but in a much less degree than any of the nonelectrolytes.

It is concluded that the introduction of the harmless nonelectrolytes which arrest the action of proteolytic enzyms should have a beneficial effect on the action of the enzyms in alcoholic fermentation. Notwithstanding the fact that zymase may also be affected by nonelectrolytes, the formation of carbon dioxid is increased with the increase of concentration of these substances until an optimum of concentration is reached. Beyond this the nonelectrolytes may entirely inhibit the action of zymase.

Some auxoamylases, E. W. Rockwood (Abs. in Proc. Iowa Acad. Sci., 23 (1916), pp. 37-39).—The author designates nitrogenous substances (particularly those containing an NH<sub>2</sub> group) which stimulate the activity of amylases as auxoamylases. In the work reported glycin, tyrosin, hippuric acid, anthranilic acid, and asparagin were found to be active, while sulphanilic acid and acid amids like urea, acetamid, and propionamid were inactive.

The effect of the amino acids as produced by digestive proteolysis on the amylolytic enzyms is indicated. The work is being continued.

Quantitative microscopy, T. E. Wallis (Analyst, 41 (1916), No. 489, pp. 357-375, fig. 1).—The author points out the common errors in the microscopical examination for adulteration, and describes a method of general applicability which obviates the usual sources of error. As a standard for comparison in the new procedure, the author uses a suspension of lycopodium spores.

An improved method of determining solubility, W. S. Hendrixson (*Proc. Iowa Acad. Sci.*, 23 (1916), pp. 31-34, figs. 2).—A simple procedure for determining solubility, in which the solution is stirred by air which has been previously saturated with moisture at the temperature for which it is desired to determine the solubility, is described in detail. This saturation of the air compensates for the usual unavoidable loss by evaporation when the stirring is accomplished by air. The apparatus was used in connection with solubility determinations of acid sodium and acid potassium phthalates, which have been proposed by the author as standards in acidimetry and alkalimetry (E. S. R., 34, p. 408).

Preparation of sulphurous acid, E. Hart (Jour. Amer. Chem. Soc., 39 (1917), No. 3, p. 376).—For the preparation of small amounts of sulphurous acid for the laboratory the author recommends the warming of fuming sulphuric acid containing 30 per cent SO<sub>3</sub> with sulphur. Lump sulphur in not too large amount should be used. It dissolves in the acid and forms a blue solution from which, on warming, SO<sub>2</sub> mixed with some SO<sub>3</sub> is given off. If SO<sub>3</sub> is objectionable, the gas obtained can be absorbed, and the resulting solution boiled to obtain the SO<sub>2</sub>. The acid which remains is still fit for most uses. The value of the procedure, in view of the saving in copper, is considerable.

An improved nephelometer-colorimeter, P. A. Kober (Jour. Biol. Chem., 29 (1917), No. 2, pp. 155-168, figs. 9).—The construction and manipulation of the new instrument, together with a simple and convenient lamp and lamp house, are described in detail. Advantages claimed for the new apparatus are a screw arrangement for changing the heights of the liquids, and, therefore, the elimination of lost motion inherent in racks and pinions; the elimination of dark cloth curtains; black one-piece glass plungers; fused one-piece nephelometric and colorimetric cups; and a convenient eye support.

The iodometric determination of sulphur dioxid and the sulphites, J. B. FERGUSON (Jour. Amer. Chem. Soc., 39 (1917), No. 3, pp. 364-373).—The author briefly reviews the methods which have been used, and points out a number of sources of error.

For the very accurate determination of large or small amounts of sulphur dioxid the excess iodin method is recommended. When carbon dioxid and sulphur dioxid are to be determined in the same sample the sulphite method can be used to advantage. For the most accurate results it is indicated that the following conditions must be observed:

"The gas sample must not come in contact with even a trace of moisture prior to its reaching the absorbent. The analyzing apparatus must be free from all rubber connectors when exact analyses of mixtures containing 10 per cent or more of sulphur dioxid are desired. For very accurate work it would be better to dispense with them entirely, although this source of error for mixtures containing less than 3 per cent of sulphur dioxid may be neglected. Mixtures of sulphur dioxid and air when dry do not react appreciably, but when moist a slow oxidation takes place. For this reason it is impossible to recover from a moist container, even by pumping, the initial amount of sulphur dioxid if the gas mixture has been in the container for any great length of time."

For the analysis of such soluble sulphites as anhydrous sodium sulphite the solution of the solid salt directly in an excess of an iodin solution containing sufficient hydrochloric acid and the determination of the excess iodin with thiosulphate is recommended. This procedure eliminates several sources of error, due to oxidation of the salt by agents other than the iodin solution.

The separation and estimation of butyric acid in biological products, I, I. K. Phelps and H. E. Palmer (Jour. Biol. Chem., 29 (1917), No. 2, pp. 199-205).—A method for the separation of butyric acid from formic and acetic acids by treating their barium salts with an excess of quinin sulphate, extracting the quinin butyrate with carbon tetrachlorid, crystallizing, weighing, and identifying it by its melting point is described.

A table showing the melting point and approximate solubility in carbon tetrachlorid of the quinin salts of formic, acetic, propionic, butyric, and sulphuric acids is submitted. The solubilities of the propionate and butyrate are so nearly the same that only a partial separation can be effected. The difference in the solubilities of the formate and propionate is, however, so much greater that their separation is effected easily.

Thiobarbituric acid as a qualitative reagent for ketohexose, G. P. Plaisance (Jour. Biol. Chem., 29 (1917), No. 2, pp. 207, 208).—The author, at the Iowa Experiment Station, recommends the use of thiobarbituric acid as a test for ketohexoses as follows:

The sample to be tested is treated in a test tube with sufficient hydrochloric acid and water to bring the acid concentration to 12 per cent. The mixture is then heated to boiling, cooled under the tap, and a few drops of thiobarbituric acid solution (in 12 per cent hydrochloric acid) added. If a ketohexose was originally present an orange-colored precipitate forms on standing; if only aldoses were present the solution may become yellow but no precipitate results. It is indicated that barbituric acid can not be used in place of the thiobarbituric acid, as the condensation product is much more soluble.

Nitrogen in amino form as determined by formol titration, in relation to some other factors measuring quality in wheat flour, C. O. SWANSON and E. L. TAGUE (Jour. Amer. Chem. Soc., 39 (1917), No. 3, pp. 482-491, figs. 5).—
The authors, at the Kansas Experiment Station, have shown "that a comparatively large amount of nitrogen in amino form, as determined by the method of precipitation with phosphotungstic acid, is an indication of certain undesirable qualities in flour. These qualities in sound flour are of the same kind as those denoted by ash and acidity. Nitrogen in amino form, as measured by formol titration, is valuable together with the determination of ash and acidity in measuring quality in flour."

It is indicated, however, that titrable nitrogen is more uniformly distributed in the wheat kernel than are the materials which determine the amount of ash and acidity. In clear and low-grade flours, therefore, as compared with patent and straight flours made from the same wheat, the increase in titrable nitrogen is not proportional to the increase in ash or acidity.

Data relative to the ash, acidity, formol titration, and total nitrogen in 10-gm. samples of mill streams, commercial patent flours, commercial straight flours, commercial clear flours, and commercial low-grade flours are submitted. They show that the lower grades of flour, such as the clear and low-grade, made from sound wheat, do not contain nitrogenous substances measured by formol titration in as large a proportion as ash and acidity.

See also previous notes (E. S. R., 30, p. 555; 33, p. 160.)

The amino-acid nitrogen content of the blood of various species, J. C. Bock (Jour. Biol. Chem., 29 (1917), No. 2, pp. 191-198).—Tabulated analytical data of the amino-acid nitrogen per 100 cc. of ox, calf, sheep, pig, cat, dog,

chicken, duck, turkey, goose, human, and placental blood, and a number of pathological specimens of human blood, and in the whole blood, plasma, and corpuscles of the calf, goose, chicken, and ox, are submitted, together with a detailed procedure for the determination of amino acids in blood. See also a previous note (E. S. R., 37, p. 14).

A rapid method for determining calcium in blood and milk, H. Lyman (Jour. Biol. Chem., 29 (1917), No. 2, pp. 169-178).—Applying the principles previously used for determining calcium in urine and feces (E. S. R., 34, p. 508), a slightly modified procedure is described for determining calcium in blood and milk. The method is simple and rapid and yields results accurate to within less than 1 per cent.

For the preparation of the calcium soap a reagent prepared as follows was used: Four gm. of stearic acid and 0.5 gm. of oleic acid are dissolved in 400 cc. of hot alcohol, 20 gm. of ammonium carbonate dissolved in 100 cc. of hot water is added, and the mixture is allowed to boil for a few moments. It is cooled and 400 cc. of alcohol, 100 cc. of water, and 2 cc. of ammonium hydroxid (specific gravity 0.9) are added, and then filtered. This solution should be perfectly clear and if well stoppered will keep indefinitely. Before using, this solution should be tested in the nephelometer for impurities. Since the introduction of 0.002 mg. of calcium in the course of the determination would result in an error of 1 per cent the importance of having reagents absolutely free from calcium is emphasized.

[Note on the Duclaux method] (Dept. Landb., Nijv. en Handel [Netherlands], Verslag. en Meded. Dir. Landb., No. 5 (1916), p. 12).—The importance of maintaining at 110 cc. the volume of the mixture being distilled after the removal of the 10 cc. fractions, especially where a mixture of several acids is being distilled, is pointed out.

The detection of small amounts of oxalic acid in wine, A. A. Besson (Schweiz. Apoth. Ztg., 55 (1917), No. 7, pp. 81-85).—The author has thoroughly studied the method of Kreis and Baragiola, which consists of treating 50 cc. of the sample in the cold with 2.5 cc. of a 5 per cent calcium chlorid solution, 2.5 cc. acetic acid, and 5 cc. of a cold saturated solution of sodium acetate, allowing it to stand for 24 hours, and then centrifugalizing and examining the residue obtained. It is indicated that 0.01 per cent of oxalic acid can easily be detected by this procedure.

The results of the study show that the concentration of the reagents has a great influence not only on the crystal form of the precipitated oxalate but also on the delicacy of the test. A reagent consisting of a solution of 20 gm, of pure crystallized calcium chlorid in 250 cc. water to which 250 cc. of acetic acid and 500 cc. of a cold saturated solution of sodium acetate are added has been found to yield excellent results. Ten cc. of this reagent is used for a 50 cc. sample of the wine.

In the course of the study it was observed that in the samples containing oxalic acid, even in amounts as small as 0.01 per cent, there was no growth of mold, indicating the preservative action of the acid, at least in respect to molds. Certain samples which originally gave positive tests for oxalic acid yielded negative tests after several weeks. The oxalic acid thus appears to be destroyed in time. No explanation is given for this phenomenon.

Researches on the ultrafiltration of milk, A. Borrino (Arch. Ital. Biol., 64 (1915), No. 3, pp. 417-425).—After having experienced some difficulty in the ultrafiltration of milk through collodion membranes the author obtained a clear

<sup>&</sup>lt;sup>1</sup> Schweiz. Apoth. Ztg., 53 (1915), No. 29, pp. 397-400.

filtrate by passing the centrifugalized milk through an alundum filter. About 250 cc. of clear filtrate was obtained in two hours by this procedure.

Comparative analytical data relative to the specific gravity, electrical conductivity, freezing point, protein, lactose, ash (soluble and insoluble), chlorin, calcium, and phosphorus of the whole milk and filtrate (cow and human), and the probable combinations between the casein, calcium, and phosphorus in the residue from the filtrate of cow's milk are submitted in tabular form. It is concluded that in human milk as well as in cow's milk the lactose is not combined with the protein. A part of the calcium and phosphorus exists free in a dissociable form. The calcium forms, not alone with the casein but also with the phosphoric acid and probably other anions, certain combinations which as yet have not been determined. These are retained by the filter and are probably to be regarded as nondissociable combinations, for the most part colloidal. In cow's milk a calcium-casein combination containing 2.4 per cent calcium oxid was determined.

In human milk the quantity of calcium and phosphorus in inorganic combination is relatively larger than that in cow's milk, representing more than one-half of the total calcium and phosphorus. In cow's milk the quantity represents less than one-third of the total.

A rapid and exact method for determining the diastatic activity of germinated grain, C. A. Nowak (Pure Products, 13 (1917), No. 3, pp. 128-131).—
The author describes in detail a rapid modified procedure which is considered to yield reliable results.

The soluble carbohydrate content of feeding stuffs as a guide in determining quality, G. B. VAN KAMPEN (Cultura, 27 (1915), No. 324, pp. 241-256).—The author briefly indicates that the results of a chemical and microscopical examination of feeding stuffs do not always yield the desired information in regard to the quality of the material.

The literature on the soluble and insoluble carbohydrates in normal and abnormal press cakes is reviewed. A procedure for determining soluble sugars polarimetrically before and after inversion is described and some experimental data submitted and discussed. While the data are considered to be only preliminary and it is deemed hardly possible to define any definite limits for sugar content of normal and abnormal samples because of the small amount of data available, the following percentage contents of sugar (calculated as sucrose) are considered normal for samples of first-grade material: Coconut cake, 17.5; soy bean cake, 13; peanut cake, 12; cottonseed meal, 7; linseed meal, 5; palm nut cake, 3.5; and sesame cake, 3.

Cane juice clarification, C. W. HINES (Philippine Agr. Rev. [English Ed.], 9 (1916), No. 4, pp. 339-347).—This is a general discussion of the common clarifiers used in cane sugar manufacture, as well as some special trade clarifiers.

Normal fermentation of sauerkraut, L. A. ROUND (Jour. Bact., 1 (1916), No. 1, p. 108).—The author has studied the fermentation of sauerkraut in two factories, in the first making microscopical and chemical examinations and in the second a bacteriological study.

It was found that bacteria alone were concerned with the fermentation proper. Wherever air came in contact with the material, as at the top of the vat, yeasts grew rapidly and produced a heavy foul-smelling scum which destroyed the acid. A vat just being filled showed the presence of 5,000,000 organisms per cubic centimeter, 80 per cent of which fermented glucose and the remaining 20 per cent being mainly yeasts. The rate of growth of bacteria and the rapidity of fermentation were found to vary directly with the temperature, being much slower in cold than in warm weather. After reaching a maximum,

the number of bacteria gradually decreased until at the end of five weeks between 4,000,000 and 10,000,000 viable organisms were present.

Vats showing abnormal fermentation contained a different class of organisms. Bad fermentations in properly salted vats were found to be due to the growth of unfavorable organisms during the first few days before the normal acid flora had been able to establish itself and produce sufficient acid to stop decomposition. A slight increase in temperature was found in the course of normal fermentation.

#### METEOROLOGY.

Relation of weather to crops and varieties adapted to Arizona conditions (Arizona Sta. Bul. 78 (1916), pp. 45-118, pl. 1, fig. 1).—"This publication is a thorough revision of Bulletin 61 (E. S. R., 22, p. 418). The arrangement and much of the body of the publication are essentially the same, but considerable new matter has been added, and information concerning the various crops and their adaptability to different parts of the State has been revised in accordance with new developments and the added experience of the past several years. This information has been secured from records which have been accumulating at the experiment station farms, and from personal visits and correspondence of the different members of the station staff throughout the State."

The records upon which the bulletin is based have now covered a period of 18 years. The bulletin deals briefly with methods of keeping weather records; factors influencing results; general effects of temperature, direct sunshine, and aridity and rainfall; and more in detail with varieties of crops which have proved most suitable to different sections of the State, arranged alphabetically for convenient reference and also with reference to the months in which they should be planted and when they mature.

Native vegetation and climate of Colorado in their relation to agriculture, W. W. Robbins (Colorado Sta. Bul. 224 (1917), pp. 3-56, pls. 4, figs. 16).—"This bulletin is an outgrowth of a number of years of observation and study of the native vegetation of Colorado in its relation to climate and to agriculture" supplemented by a reconnoissance survey especially of the west middle portion of the State during the summer of 1916, which was undertaken "for the purpose of testing conclusions arrived at and finding new relations."

In this study little consideration has been given "to the question of the value of native plant life as an indicator of the local physical conditions of the environment. Such detailed study, however, is of much practical importance, and it is planned to engage in such a study later. But the attempt here is to point out the broader relations between our large native plant associations and the principal climatic factors under which they are growing, and to show their relation, in a very general way, to Colorado agriculture." Data, original and compiled, on temperature of the surface of the plant, air, and soil, with different altitudes, slopes, and other conditions; length of frostless season and effects of frosts and freezes; amount and distribution of precipitation under varying conditions; humidity; and sunshine, are presented and discussed.

"The following large communities of Colorado native plants, with their climatic and agricultural relations, are discussed: (1) Grass-steppe or short-grass-land (Great Plains); (2) shrub-steppe—sagebrush, greasewood, rabbitbrush, etc.; (3) chaparral or brushland (thicket)—oakbrush, buckbrush, willow thicket, chokeberry, thornapple, mountain mahogany, etc.; (4) coniferous woodland—pinyon pine and juniper woodland; (5) coniferous forests—(a) yellow pine-Douglas fir forest, (b) white fir forest, (c) lodgepole pine forest, (d) Engelmann spruce-balsam fir forest."

The grass-steppe is stated to be "a vegetative response to a low, infrequent rainfall, the greater percentage (approximately 75 per cent) of which comes during the growing season, and about 60 per cent of which is during the four months, June, July, August, and September." The average annual temperature for the steppe area ranges from 45 to 56° F. The relative humidity is generally low, from about 50 to 55 per cent. The grass-steppe is indicative of temperature conditions favorable to a varied agriculture when sufficient moisture is supplied.

The shrub-steppe, which is scattered throughout the entire intermountain area, and occupies nearly 25 per cent of the area of the State, is as a rule representative of good general farming and orchard lands. The most important and by far the most extensive vegetation of the shrub-steppe is sagebrush, which is the characteristic type of vegetation of the well-drained, nonalkaline arid districts of western Colorado. Types of shrub-steppe vegetation of secondary importance are greasewood and rabbitbrush, which cover the larger part of San Luis Valley and limited areas in other parts of the State. Greasewood is not indicative of any particular set of climatic factors, but is a response to local soil conditions. It is, however, almost always an indication of a high water table and consequently of soil rich in alkali. "The round-leaved saltbush (Atriplex confertifolia), sometimes along with greasewood (Sarcobatus vermiculatus), and common Grayia (Grayia spinosa), is found chiefly on alkaline flats in western Colorado, especially in the lower valleys. Extensive and typical areas of this association are found in the lower Snake River Valley. The soil it occupies is usually fine-grained, the surface layers dry, and the soil below the first and second foot quite high in salt content. Salt sage or small saltbush (Atriplex nuttalli) is another plant of alkaline flats."

Scrub oak forms the most extensive growth of chaparral or brushland and grows under a wide range of climatic conditions as found between 4,000 and 9,000 ft. It is frequently associated with buckbrush, and both usually occupy deep rich soil. Scrub oak forms are seldom found above the limit of successful growth of alfalfa, potatoes, small grains, strawberries, hardy can fruits, and the hardy vegetables.

The pinyon pine-juniper woodland zone is confined to a region of which the mean annual precipitation is uniformly under 15 in. It is an index "of temperature conditions which permit the growth of all but the tenderest fruits, all the small grains, flax, sugar beets, potatoes, alfalfa, and the garden vegetables, excluding melons. In the lower part of the belt peaches, sweet cherries, melons, and other tender crops yield bountifully. Much valuable orchard land of Cologado is cleared pinyon pine-juniper soil."

Yellow-pine forests seldom show typical development in areas having less than 15 in. of precipitation annually. Its altitude ranges approximately from 6,000 to 8,000 ft. in northern Colorado and 7,000 to 9,000 ft. in southern Colorado. A large percentage of the area of growth of this plant is so steep and stony as to be economically adapted only to grazing and timber growing. Yellow-pine forest indicates temperature conditions favorable to the maturing usually of wheat, oats, barley, and rye, and is well suited to alfalfa, potatoes, and the hardier vegetables, cane fruits, and strawberries.

"Lodgepole pine, as a strongly developed plant association, indicates temperature conditions too low for the maturing of the small cereals, for the profitable growth of alfalfa, potatoes, peas, and any but the most hardy vegetables." The same is true of the white-fir forest zone. Engelmann fir occupies a region of nonagricultural climatic conditions.

Weather conditions, 1911-1916 (Minnesota Sta., Rpt. Crookton Substa., 1910-1916, pp. 14-19).—Tables are given which show the precipitation by months and the dates of the latest killing frost in the spring and the earliest

in the fall at Crookston, Minn., from 1897 to October 1, 1916, and summaries of observations on temperature, precipitation, clear and cloudy days, and prevailing winds during the same period. The average date of the earliest killing frost was September 24, the average growing period being 127 days.

#### SOILS-FERTILIZERS.

Soil survey of New Castle County, Delaware, T. M. Morrison, W. d. Seward, and O. I. Snapp (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 84, fig. 1, map 1).—This survey, made in cooperation with the Delaware Experiment Station, deals with the soils of an area of 278,400 acres in northern Delaware, two-thirds of which lie in the Coastal Plain and one-third in the Piedmont Plateau. The surface includes a smooth to rolling plain in which drainage is not yet thoroughly established, and a well-drained and deeply dissected plateau.

Including tidal marsh and meadow, 16 soil types of six series are mapped, of which the Sassafras silt loam and loam and the Chester loam cover 26.5, 12.4, and 11.9 per cent of the area, respectively.

Analyses of soils of Habersham County, W. A. Worsham, Je., D. D. Long, L. M. Carter, and M. W. Lowey (Bul. Ga. State Col. Agr., No. 114 (1917), pp. 40, figs. 5).—This report is intended to supplement the physical survey of the soils of the county made in cooperation with the Bureau of Soils of the U. S. Department of Agriculture, and contains data on the chemical composition of both the surface soil and subsoil of the various soil types found in the county.

"Taking the average of all soils of the county, analyses show the plant food content to be as follows: Nitrogen, 0.0425 per cent; phosphoric acid, 0.0616; and potash, 1.0126. Nitrogen and phosphoric acid are relatively low in the average soil of the county. Nitrogen is lowest, and, without doubt, the limiting factor of crop production."

Bremer County soils, W. H. Stevenson, P. E. Brown, and F. B. Howe (Iowa Sta. Soil Survey Rpt. 1 (1917), pp. 48, pl. 1, figs. 11).—This is the first of a series of reports on the soils of Iowa, and supplements the survey made in cooperation with the Bureau of Soils of the U. S. Department of Agriculture (E. S. R., 32, p. 317).

Analyses of samples of the soils taken at depths of  $6\frac{2}{3}$  in.,  $6\frac{2}{3}$  to 20 in., and 20 to 40 in., are reported. "These results, as a whole, show that the soils of Bremer County are not so richly supplied with necessary plant food as to assure abundant crop growth continuously. . . . In general the application of phosphorus, the increase of humus and of nitrogen, and the addition of limestone are needed to make the soils of the county permanently fertile. Other essential elements are apparently present in sufficient amounts for many years to come."

General information regarding the principles of permanent soil fertility and the results of greenhouse tests of some of the prevailing soil types of the county are included.

Soil survey of Richardson County, Nebraska, A. H. Meyer, P. H. Stewart, and C. W. Watson (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 36, fig. 1, map 1).—This survey, made in cooperation with the University of Nebraska, deals with the soils of an area of 348,800 acres in southeastern Nebraska, the topography of which is in general rolling. The surface drainage is considered to be adequate. The county lies almost entirely within the glacial and loessial region, with only a small area belonging to the river flood plain province.

The soils include upland, terrace, and first bottom soils. Including river wash and rough stony land, 14 soil types of nine series are mapped, of which

the Carrington silt loam, Wabash silt loam, and Marshall silt loam cover 46.5, 19.6, and 16.5 per cent of the area, respectively.

Soil survey of Hamilton County, Ohio, A. L. Goodman, E. R. Allen, and S. W. Phillips (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 39, ftg. 1, map 1).—This survey, made in cooperation with the Ohio Experiment Station, deals with the soils of an area of 260,480 acres in southwestern Ohio, the topography of which ranges from level or nearly flat to hilly, ridgy, and rough. Drainage in general is said to be well established.

The soils consist of upland, terrace, and bottom land. "The soil-forming material is complex in origin as well as in mode of accumulation. It is partly glacial drift or till, partly residual material left in the decay of limestone and calcareous shales, partly a smooth, silty material whose origin is not thoroughly understood, and partly alluvium." Seventeen soil types of ten series are mapped, of which the Cincinnati silt loam and the Fairmont silty clay loam cover 38 and 24.8 per cent of the area, respectively.

Agricultural possibilities of Ohio peat soils, A. Dachnowski (Jour. Amer. Peat Soc., 9 (1916), No. 1, pp. 10-21).—This is a report of rather general observations on the necessary fertility treatment of Ohio peat soils, including cultivation, liming, fertilization, drainage, and cropping. It is concluded that "the essential objects are, aside from more effective organization, an increase in smaller farms, a greater use of fibrous soils for pasture, meadow, or general livestock farming, and more intensive farming and greater specialization upon the better, suitable types of peat and muck."

Study of the vine-growing soils of Vevey [Switzerland], I. ANKEN (Ann. Sci. Agron., 4. ser., 5 (1916), No. 1-6, pp. 1-156, pls. 3, figs. 4).—This is the report of a survey of the geology, origin, mineralogy, and mechanical, physical, and chemical composition of the vine soils of the district of Vevey on the northern shore of Lake Geneva in Switzerland.

The soils of Southern Rhodesia and their origin, H. B. Maufe (Rhodesia Agr. Jour., 14 (1917), No. 1, pp. 8-23).—The soils of Southern Rhodesia are discussed as red clay, granite, sandy, and black soil, and mechanical analyses of samples of the last three are given. It is stated that the soils of the regions are mainly the result of the decomposition of rocks and that clayey matter consisting of hydrated aluminum silicates is the chief product of that decomposition.

The soil mulch, L. E. Call and M. C. Sewell (Jour. Amer. Soc. Agron., 9 (1917), No. 2, pp. 49-61).—Experiments conducted at the Kansas Experiment Station, in which moisture determinations were made to a depth of several feet on cultivated and uncultivated, uncropped areas, kept free from weeds, are reported.

The results are taken to indicate that "a cultivated soil is no more effective than a bare uncultivated soil in preventing evaporation. Cultivation conserves soil moisture by the elimination of weeds and by preventing run-off. The development of nitrates may be as extensive without cultivation as with cultivation."

Relation between indications of several lime-requirement methods and the soil's content of bases, C. J. Schollenberger (Soil Sci., 3 (1917), No. 3, pp. 279-288, figs. 3).—Laboratory experiments conducted at the Ohio Experiment Station on two soils well supplied with basic material other than carbonates and data obtained from analyses of soil from the 5-year rotation fertility experiment plats at the station are reported. The soils were neutral clay loam deficient in organic matter, alkaline black clay, and acid silt loam.

"Experiments upon acid-extracted and washed soils and upon field-treated soils demonstrate that the vacuum method is, of the number studied, the most nearly quantitative method which is at the same time universally applicable.

The idea of determining the percentage of total lime requirement satisfied is offered as a means of comparing the condition of basicity of different soils and as an aid in the solution of other soil problems. The limited amount of experimental data available indicates that there may be some relation between the percentage of total lime requirement satisfied and the reaction of the soil to litmus, carbonates being practically absent. Crop yields in pot experiments have not indicated that an application of precipitated calcium carbonate, according to the indications of the vacuum method, which is considered to represent saturation with calcium, is harmful in other than exceptional cases."

Four references to literature bearing on the subject are appended.

The effect of some acids and alkalis on soil bacteria in the soil solution, O. M. Gruzit (Soil Sci., 3 (1917), No. 3, pp. 289-295, figs. 2).—This is an abstract of a thesis, in which experiments conducted at the Michigan Agricultural College on solutions extracted from rich, sandy loam and sandy soils are reported.

"The solutions were adjusted to various degrees of reaction with N/100 sodium hydroxid and hydrochloric acid, methyl red being used as an indicator for titration, and 10-cc. quantities were placed in 100 gm. of pure sterile quartz sand. The moisture content of the cultures was adjusted about every ten days. The counts of bacteria in the soil solution were made upon sodium asparaginate agar after seven days of incubation at a temperature varying between 19 and 23° C."

It was found that "the development of the general flora of the soil bacteria from sand and sandy loam soils, when studied in the soil solution of sand cultures, was retarded if the reaction of the medium had a higher OH-ion concentration than N/1,000. The development of soil bacteria was inhibited when the reaction of the medium became neutral. The H-ion concentration of N/1,200 hydrochloric and sulphuric acids was germicidal to about 99.2 per cent of soil bacteria. . . . With H-ion concentration of N/2,164 the rate of multiplication of soil bacteria from sandy loam corresponded to the rate of destruction so that there was no change in the total number of bacteria. The H-ion concentration of N/2,840 inhibited the growth of 43 per cent of soil bacteria when compared with the growth of soil bacteria in the medium with N/412 OH-ion concentration. The reaction of alkaline cultures was gradually neutralized and later became acid. When the 'toxic limit' of acids toward Indian corn seedlings was compared with the toxic limit of about the same concentration of the same acids on the general flora of the soil bacteria from sand and sandy loam soils, the soil bacteria were injured to the extent of 43 per cent."

Twenty references to literature bearing on the subject are appended.

A review of investigations in soil protozoa and soil sterilization, N. Kopeloff and D. A. Coleman (Soil Sci., 3 (1917). No. 3, pp. 197-269).—This paper is intended to be a survey of the subject to date and includes a list of 337 references to literature bearing on the subject.

The ecological significance of soil aeration, W. A. CANNON and E. E. Free (Science, n. ser., 45 (1917), No. 1156, pp. 178-180).—Experiments conducted by the Carnegie Institution of Washington and Johns Hopkins University are reported, which show "that different species of plants may differ markedly in their response to variations in the composition of the soil atmosphere, and hence to changes in soil aeration. The effects of diminution of oxygen are manifest and the results with Opuntia indicate a direct and specific effect of carbon dioxid in addition to the effect of the dilution of the oxygen."

It is pointed out that "although deficiency in aeration has frequently been suggested as an agricultural difficulty, or as the reason why certain species do not grow upon soils of heavy texture, it does not appear that this suggestion

has had any exact experimental basis. Nor does it seem to have been appreciated that different species may have great differences in the oxygen requirement of their roots and widely variant responses to differences in soil aeration, responses which appear to be quite as specific and significant as the responses to temperature and to available water which form the present basis of ecological classification."

Reclaiming the waste, P. A. Graham (London: Country Life, Ltd.; New York: Charles Scribner's Sons, 1916, pp. XIII+175; rev. in Country Life [London], 41 (1917), No. 1050, pp. 149, 150).—This book is a number of the so-called "Increased Productivity Series." Its object is "to direct attention to the vast possibilities of waste land reclamation in Great Britain and Ireland." It contains the following chapters:

The urgency of land reclamation; reclaiming a Norfolk heath (March 9, 1916); reclaiming a Norfolk heath—four months' progress (July 12, 1916); the weeds of a Norfolk heath, by Brenchley; how to hold reclaimed waste; nowt but bracken and fuzz; how much reclaimable waste is there; sand dunes and coast erosion; poverty bottom—a lesson from downland; reclamation of waste land in Holland; reclamation in Holland—a colonial minister's experience; making farms out of moorland; fish ponds and reclamation; reclamation in Belgium, by H. Vendelmans; a war of timber; afforestation of peat bogs and sand dunes, by A. Henry; planting on the South Downs, by Somerville; reclaiming the pit bank; labor and reclamation; forestry and reclamation; and the industrialization of land in France, by Souchon.

The apparent main purpose of this book is to outline ways and means of meeting war-time conditions in England.

Summaries of soil fertility investigations, A. T. Wiancko and S. C. Jones (Indiana Sta. Bul. 198 (1917), pp. 5-20).—This bulletin presents in a condensed form the principal results obtained up to the present time from the use of lime, legumes, manure, and various commercial fertilizers upon seven outlying experiment fields and upon one of the older series of plats on the university farm.

Excluding two fields which have been under treatment only one year, the following results have been secured from the principal treatments: With ground limestone the profits have ranged from \$3.31 to \$18.34 per acre per rotation, and with manure from \$1.62 to \$4.45 per ton per rotation. On limed land mixed fertilizers have been used at a profit in all cases. At North Vernon (Jennings Co.) and Worthington (Greene Co.), where fertilizers were applied to wheat on manured land, good wheat increases were secured with a 200-lb. application of a fertilizer carrying 2 per cent nitrogen, 8 per cent phosphoric acid, and 4 per cent potash following corn, which had received 6 tons of manure and 200 lbs, of acid phosphate per acre.

Rock phosphate without manure has yielded profitable returns at Scottsburg (Scott Co.) and Wanatah (Laporte Co.). With manure it has been profitable at North Vernon and Worthington, while at Scottsburg and South Bend (St. Joseph Co.) it has been used at a loss. Acid phosphate, with or without manure, has shown large profits in all cases, and per dollar invested has been the most profitable fertilizer treatment either alone, with lime, or with both lime and manure.

Clover in place of timothy in rotation with corn and wheat has increased the value of the rotation by \$8.07 at North Vernon and \$7.80 at Worthington, where no fertilizer was used. On fertilized land the legume has increased the value of the rotation by \$12.50 and \$5.08, respectively, after paying for the fertilizer.

Why Illinois produces only half a crop, C. G. Hopkins (Illinois Sta. Circ. 193 (1917), pp. 3-16).—In this address before the Illinois State Farmers' Institute, at Streator, February 21, 1917, the author analyzes the Illinois crop

yields and reviews experimental data relative to increased yields due to improved soil fertility methods,

It is concluded that both the average acre-yields and the average acre-values of the most common Illinois crops (corn, oats, wheat, and clover) on the most common Illinois soil can be doubled by the adoption of better crop rotations, including a more liberal use of legumes, with a return of more organic manures, together with a systematic application of limestone and phosphorus in the form of raw rock phosphate but without commercial potassium or commercial nitrogen.

Live stock and the maintenance of organic matter in the soil, E. O. FIPPIN (Jour. Amer. Soc. Agron., 9 (1917), No. 3, pp. 97-105, fig. 1).—This is a review and summary of the results of work by others at several of the State experiment stations, from which the following conclusions are drawn:

"The higher plants are able to use organized carbonaceous foods, both nitrogenous and nonnitrogenous. Carbonaceous food conserves energy in the process of growth of the crop and makes possible a larger total growth in a given time. The organic matter in the soil is the direct source of the carbonaceous material used by the plant. Any process that permits the destruction of organic matter that might find its way into the soil is likely to be poor economy.

"Animals destroy from half to nine-tenths of the organic matter in the feed consumed. It is burned up in the body processes and expended as energy. A further large loss occurs in the handling of the manure.

"It is entirely possible to maintain the organic matter in the soil without animal husbandry. On very poor soils, animal husbandry may be bad practice. It may be justified by large profits from the animal products by means of which the loss of organic matter can be made up from other sources."

The manual of manures, H. Vendelmans (London: Country Life; New York: Charles Scribner's Sons, 1916, pp. XVI+164, figs. 6).—This is a number of the so-called "Increased Productivity Series," and its purpose is to give practical information on manures and fertilizers and their proper uses. A discussion of manures in general is followed by specific information regarding nitrogenous, chemical, phosphatic, and potassic manures, ashes and soot, magnesia and silica, and organic manures of different kinds. Materials for soil improvement, including lime-containing compounds, are also discussed, and final sections deal with auximones and the quantities of manures to be used per acre.

The text of the English fertilizers and feeding-stuffs act is also given.

Fertilizers and their supply in war time, J. A. VOELCKER (Jour. Roy. Soc. Arts, 65 (1917), No. 3356, pp. 324-337).—The purpose of this paper is to summarize the present general agricultural requirements in England in regard to fertilizers as consisting in the supply of superphosphate and basic slag as phosphatic manures and of ammonium sulphate as the nitrogenous one. "The supply of these three is all essential, and if farmers are to meet successfully the demands now made on them, it is all important that they should be put in the way of obtaining an adequate and ready supply of these."

Artificial manures.—Experiments on their value for crops in western India, H. H. Mann and S. R. Paranjpe (Dept. Agr. Bombay Bul. 76 (1915), pp. 55).—This bulletin gives the results of a number of fertilizer experiments with various crops in western India, where commercial fertilizers have not proved popular heretofore. The crops were divided into field crops, which included tobacco, potatoes, wheat, cotton, and sugar cane, and garden crops, which included chillies, onions, alfalfa, and bananas.

A general conclusion which seems applicable to all districts alike is that where irrigation is not practiced an application of commercial fertilizers is not so profitable as the fertilizing methods already in practice. The use of acid phosphate on the black soils of western India gives good results, providing there is a considerable quantity of organic matter present in the soil.

[Fertilizer experiments], P. LIECHTI (Landw. Jahrb. Schweiz, 30 (1916), No. 5. pp. 506-508).—Mixing liquid manure with peat dust was found not to prevent the escape of ammonia from the liquid manure.

Experiments with oats on an acid sandy loam soil, to compare samples of lime nitrogen from five different sources showed that in one case the effect of the lime nitrogen was injurious. Analyses of samples of this lime nitrogen showed the presence of appreciable quantities of dicyandiamid, which is thought to explain the injurious action.

Incomplete experiments with urea on oats are also reported.

Standardization of humus used for fertilizer, J. H. Hoff (Jour. Amer. Soc., 10 (1917), No. 1, pp. 18-22).—It is the author's opinion, based on a review of work by himself and others, that the important factors in properly judging the manurial value of muck and peat are (1) natural productivity, (2) reaction and freedom from excess moisture. (3) whether high in nitrogen and whether the other fertility elements are properly balanced and proper bacterial flora prevail, and (4) solubility.

The organic nitrogen compounds of soils and fertilizers, E. C. Lathbop (Jour. Franklin Inst., 183 (1917), Nos. 2, pp. 169-206; 3, pp. 303-321; 4, pp. 465-498).—This article summarizes the results of investigations, partly reported elsewhere (E. S. R., 32, p. 217; 36, p. 25), which were undertaken to determine the origin, chemical composition, biochemical changes, and distribution of organic nitrogenous substances in the soils, as well as the action and availability of the nitrogen of soils, peats, and organic fertilizers. The investigations of others, as well as of the author, are reviewed, and an extensive bibliography of the subject is given. The studies were made with a large number of soils from widely different regions. The methods employed are fully described.

The author concludes that "histidin, hypoxanthin, cystosin, xanthin, nucleic acid, creatinin, cyanuric acid, or its isomer cyamelid, may be considered to be organic nitrogenous constituents commonly occurring in soils. Arginin, lysin, adenin, cholin, [and] trimethylamin may be considered at the present time to be nitrogenous constituents unusual to soils, inasmuch as they occur infrequently in soils. These compounds may either not be normally formed by the processes of change taking place in the soil or if they are formed they are probably very quickly changed into other compounds, for example, arginin into ornithin and urea or adenin into hypoxanthin,"

Studies were made of the nitrogenous compounds of natural and processed organic fertilizers. In the first nitrogen was found to be present in the form of ammonia, melanin, cystin, arginin, histidin, lysin, monoamino compounds, and nonamino compounds. In the second there were found arginin, histidin, lysin, leucin, tryosin, guanin, and hypoxanthin. The conclusion was reached that "the process by which the nitrogen of certain trade wastes, such as hair, leather, garbage, etc., is made more available is recognized as a process of partial hydrolysis of the complex proteins contained in such materials resulting in ammonia, amino acids, etc., all of which are more readily available than the original protein materials. This hydrolysis is almost complete, the nitrogenous compounds formed being principally the primary products of protein hydrolysis, together with a small amount of proteose-like compound which has not been fully decomposed. . . . The more extended and final the hydrol-

ysis the more available the nitrogen of the compounds formed, since, as has been shown, the final products of hydrolysis are utilized by the plants as such and are at the same time more readily changed into ammonia by soil organisms than are the intermediate compounds produced by partial hydrolysis."

Sources of nitrogen compounds in the United States, C. G. GILBERT (U. S. Senate, 64, Cong., 1. Sess., Doc. 471 (1916), pp. 11; abs. in Nature [London], 98 (1917). No. 2466, pp. 431, 432).—This is an article on the natural occurrence of nitrogen and its adaptability to use, especially as a fertilizer. In summarizing the situation it is stated that "the evolution of a practicable process for the oxidation of by-product ammonia to render present resources available, with the development of an atmospheric nitrogen fixation output by the cyanamid process carefully timed to meet growing demands following a reduction in the retail price of nitrogenous fertilizer, would appear to be the desirable governmental procedure as being the one least liable to disastrous consequences."

The nitrate industry. E. Cuevas (New York: W. S. Myers, 1916, pp. 61, pls. 3, figs. 4).—This is a paper presented at the second Pan American Congress at Washington, D. C. It gives a brief history of the Chilean nitrate fields and describes in detail the character and composition of the nitrate deposits as well as the methods of mining and preparing the material for industrial purposes.

The author is of the opinion that the deposits are capable of supplying the needs of the world for at least 300 years. It is suggested that as a matter of national preparedness, from both the military and the purely agricultural standpoint, the United States should proceed at once to buy and store large quantities of the nitrate.

In an introductory note by the publisher, attention is called to the fact that "the Central Empires of Europe imported from Chile in the five years ended December 31, 1914, an unheard of tonnage of nitrate of soda, amounting to about 5,000,000 tons. The area of the Central Empires is hardly greater than the combined areas of California and Texas. These empires imported more than all the rest of Europe for the period named. It is not improbable that a very great amount of this 5,000,000 tons is still held in reserve in Germany, and it is privately reported that no Chilean nitrate is to be permitted to be used in agriculture for some time to come."

When are summer crops to be fertilized with lime nitrogen? P. Wagner (Deut. Landw. Presse, 43 (1916), Nos. 18, pp. 149, 150; 19, pp. 158, 159).—Data relating to the time of fertilizing summer crops with lime nitrogen, obtained from numerous experiments carried on at different stations, are reported.

It is concluded that it is not necessary to apply lime nitrogen to loam and clay soils previous to seeding time. On heavy soil the ground should be worked with a harrow as early as possible and lime nitrogen applied and thoroughly mixed with the soil just prior to seeding. Better results were obtained by applying all the lime nitrogen just prior to seeding than by applying a part as a top-dressing.

Fertilizer experiments (Minnesota Sta. Rpt. 1916, pp. 58, 59).—The results of several years' fertilizer experiments at the different Minnesota experiment farms are taken to indicate "that the experiment station is not justified in recommending the use of phosphates in general farming operations in this State."

Phosphate rock, R. W. Stone (U. S. Geol. Survey Bul. 666-J [1917], pp. 4).—This is a brief review of the phosphate rock resources of the United States and Includes data on production. It is stated that the total output for 1916 was 1,980,000 tons, valued at \$5,897,000.

Potash in agriculture, B. C. Aston (Jour. Agr. [New Zeal.], 11 (1915), No. 4, pp. 283-295, figs. 3; 13 (1916), No. 6, pp. 446-454).—This is a review of the natural sources of potash in New Zealand, from which it is concluded "that only for special crops, such as potatoes, garden crops, mangels, and a few other potash-loving crops, are New Zealand soils immediately in need of potash manuring, and it is with these crops and with reclaimed swamps deficient in potash that experiments might be instituted to determine whether the deficiency may be economically supplied by resources available in the Dominion. Researches having as their object the extraction of potash with a view to its export might well give place to others having a greater prospect of economic success."

The volatilization of potash from cement materials, E. Anderson and R. J. Nestell (Jour. Indus. and Engin. Chem., 9 (1917), No. 3, pp. 253-261, figs. 13).—

The results of an extended series of investigations on potash volatilization from silicate mixtures are reported, which are taken to indicate that "the potash in any cement material can all be volatilized. The determining factors in this reaction are temperature and the length of time exposure of the cement material to the temperature and gas volume prevailing. The lower limit of temperature for potash volatilization is  $1{,}100^{\circ}$  C., and the rate of volatilization increases rapidly with the temperature.

"The presence of chlorids, particularly calcium chlorid, increases the velocity of the volatilization, while sulphates decrease this rate. Because of the formation of sulphates, sulphur dioxid in the furnace gases retards the volatilization. Sodium is driven off nearly as easily as is the potassium.

"In the kiln, besides the factors of time and temperature, the size of the clinker also affects the volatilization rate. The smaller the clinker the better the volatilization of potash from it.

"Although the potash in any cement mix can be driven off, the rate of expulsion at any given temperature varies for different materials, and is probably dependent on the mineralogical character of the potash-bearing component of the cement material."

Growing crops without potash in 1916, C. D. Woods (Agr. of Maine, 1915, pp. 293-307).—This paper is a reprint of that previously noted (E. S. R., 35, p. 325).

Lime in agriculture, E. A. Felder (S. C. Dept. Agr., Com. and Indus., Bul. 59 (1917), pp. 75, flgs. 2).—This bulletin is intended to be a complete treatise on the subject, discussing the varied forms of agricultural lime and their uses, sources of supply, and the relative values of limestone, shell lime, calcined marl, and noncaustic, dried phosphomarl in South Carolina agriculture. It is stated that liming is the greatest need of South Carolina agriculture and that marl is the greatest undeveloped asset of the State in this respect. Special attention is given to the intelligent use of lime.

Forms of agricultural lime and their application, M. L. Fearnow (Nat. Lime Manfrs. Assoc., Agr. Bul. 3 (1917), pp. 16).—This pamphlet deals with ground limestone, quicklime, and hydrated lime with reference to their advantages and disadvantages for agricultural use, pointing out especially the conditions under which each may best be used.

The relation of lime to agriculture, L. B. Broughton (Md. Agr. Ext. Serv. Bul. 2 (1916), pp. 25-56).—This bulletin discusses different lime-bearing compounds and their physical, chemical, and biological effects on soil, and summarizes the results of experiments at the Maryland Experiment Station on the effect of lime in increasing crop production.

The summarized results are taken to indicate that "physically even a small amount of lime carbonate by its solubility in the carbonated soil water will act

beneficially in causing the flocculation of clay and in the subsequent conservation of the flocculent or tilth condition, by acting as a light cement holding the soil crumbs together when the capillary water has evaporated, thus favoring the penetration of both water and air, and of the roots themselves. Among the most important chemical effects are, by neutralizing the soil acidity, the maintenance of fertility is raised; by maintaining the proper degree of moisture and warmth bacterial life is enhanced, especially that of mitrification, also the development and activity of root bacteria of legumes and other nitrogen-gathering bacteria; the rendering available, directly or indirectly, of relatively small percentages of plant food, notably phosphoric acid and potash."

The text of the Maryland lime-grinding bill is included.

The question of lime fertilization, P. Liechti and E. Trunninger (Landw. Jahrb. Schweiz, 30 (1916), No. 5, pp. 480-488, figs. 2).—Experiments on the influence of liming on soil fertility are reported, and the conclusion drawn that more attention should be given to the size of the grains of calcium carbonate used for fertilizing purposes. It is thought that the use of the finest ground calcium carbonate is not justified in all cases, but that coarse calcium carbonate should be used where experience has shown that the soil fertility is injured by excessive liming or by a liming which is quickly effective. It is believed that by the use of coarser ground lime a more uniform distribution on the soil can be obtained, and that more can be used without injuring soil fertility.

Liming the land.—Decomposition and utilization of limestone in soil, J. W. Ames and C. J. Schollenberger (Mo. Bul. Ohio Sta., 2 (1917), No. 4, pp. 121-124).—This is a review of experience at the station, the results of which are thought to "furnish conclusive evidence and emphasize the fact that the larger part of light and moderate applications of ground limestone, when applied to a soil in need of lime and similar to the silt loam at the station, decomposes within a year. Even at the end of five years, 'however, traces remain; this may be due to the superior resistance of the larger particles contained in the ground limestone. Other experiments have shown that limestone screenings (\frac{1}{2} to \frac{1}{2} in.) are very slowly decomposed, indicating that they have but slight value unless applied in excessive amounts.

"The data indicate that although there is a considerable loss of bases when limestone is applied to the soil at any rate, such loss is excessively large when the rate of application greatly exceeds the amount which can be absorbed by the soil.

"Small or moderate applications frequently repeated would probably pay better in the final analysis than large applications at less frequent intervals."

The fertilizing value of wastes from the hemp industry, A. Draghetti (Staz. Sper. Agr. Ital., 49 (1916), No. 5-6, pp. 324-333).—This is a brief description of the hemp treating process and a review of different analyses of the waste liquors and materials from the process.

[Fertilizers, season 1915-16], B. B. Ross (Ala. Dept. Agr. Bul., 7 (1916), No. 75, pp. 96).—This bulletin reports the results of actual and guaranteed analyses of 466 samples of fertilizers and fertilizing materials offered for sale in Alabama during the fiscal year ended September 30, 1916, together with general information on the classification of fertilizer materials and formulas for home mixtures, the text of the Alabama fertilizer law, and a list of concerns licensed to sell fertilizers in the States during the year.

Analyses of commercial fertilizers, ground bone, and agricultural lime, C. S. CATHCART ET AL. (New Jersey Stas. Bul. 303 (1916), pp. 5-52).—Supplementing previous work (E. S. R., 36, p. 429), this bulletin contains the results of actual and guaranteed analyses of 283 samples of fertilizers and fertilizing materials, 43 samples of ground bone, and 35 samples of agricultural lime

collected for inspection in New Jersey during 1916, together with a list of brands registered for sale.

Analyses of fertilizers and cottonseed meal, B. W. KILGORE ET AL. (Bul. N. C. Dept. Agr., 37 (1916), No. 10, pp. 86).—This report contains the results of actual and guaranteed analyses of 1,371 samples of fertilizers and fertilizing materials and 187 samples of cottonseed meal collected for inspection in North Carolina during the fall of 1915 and the spring of 1916.

List of fertilizer and lime manufacturers and importers (*Penn. Dept. Agr. Bul. 289* (1917), pp. 47).—This bulletin gives the texts of the Pennsylvania fertilizer, bone, and lime laws, and a list of fertilizer manufacturers and brands of fertilizers licensed for sale during 1917.

# AGRICULTURAL BOTANY.

Plant physiology as horticultural theory, H. Molisch (Pflanzenphysiologie als Theorie der Gärtnerei. Jena: Gustav Fischer, 1916, pp. X+305, figs. 128).— The seven sections of this book, which is intended primarily for horticulturists, deal principally with plant nutrition, respiration, growth, freezing and frost killing, reproduction, germination of seeds, and variability, inheritance, and plant breeding.

Applied and economic botany, H. Kraemer (Philadelphia: Author, 1916, 2. ed., pp. VIII+822, pls. 2, figs. 420).—In the present edition (E. S. R., 33. p. 27), the text has been revised, bringing the work up to date. Among the portions added are a glossary and a concise statement regarding the nature and properties of vitamins.

Canaigre, a quick-growing tannin plant for acclimatization in France, A. Piédallu (Compt. Rend. Acad. Sci. [Paris], 163 (1916), No. 20, pp. 575, 576).—This is a discussion of canaigre (Rumex hymenosepalus) as a rapidly growing and abundant source of tannin to take the place of the oak and chestnut trees destroyed by military activities in portions of France.

New names in Amygdalus, P. L. RICKER (Proc. Biol. Soc. Wash., 30 (1917), pp. 17, 18).—It has been considered necessary, in accordance with present usage, to make several transfers from Prunus to Amygdalus. A list is given of such recent transfers, resulting in 14 species of Amygdalus.

Studies in the nomenclature and classification of bacteria. The problem of bacterial nomenclature, R. E. Buchanan (Jour. Bact., 1 (1916), No. 6, pp. 591–596).—The author expresses the view that the present time is propitious for the careful formulation of general rules of bacteriological nomenclature and of a general scheme of bacterial classification. Regarding this work several suggestions are offered.

Preliminary note on the classification of some lactose-fermenting bacteria, M. Levine (Jour. Bact., 1 (1916), No. 6, pp. 619-621).—A key is given which is said to be the result of a study of 333 lactose-fermenting organisms isolated from soil, sewage, and animal sources. The subdivisions proposed are not based upon single characters but upon differences in groups of characters. The names employed are considered as tentative only.

The preparation of culture media from whole blood, R. A. Kelser (Jour. Bact., 1 (1916), No. 6, pp. 615-617).—Describing the method employed in the preparation of a whole blood culture medium, said to be more easily and quickly prepared than ordinary beef infusion and to be inexpensive and well adapted to organisms which do not thrive well on ordinary culture media, the author states that this can practically replace the more difficult preparation serum agar. A concentrated extract from blood, which was still further reduced by evaporation, proved satisfactory as a culture medium.

The development of Azotobacter, A. Cauda (Staz. Sper. Agr. Ital., 49 (1916), No. 2, pp. 125-131).—Details are given of a study during several years of Azotobacter, as regards its morphology, its relationships, and its physiology as influenced by salts of phosphoric acid, by calcium carbonate, by magnesium and nitrogen compounds, by humus and various other soils, and by association with other organisms.

The soils which are rich, well worked, and provided with humus and mineral fertilizers, prove to be those in which the development of Azotobacter is most active. This fact agrees with the observed results obtained from practice on well-managed farms.

The oxygen requirements of biological soil processes, T. J. Murbay (Jour. Bact., 1 (1916), No. 6, pp. 597-614).—In the work here detailed, which was planned to test the relative influence of aerobic and anaerobic conditions on some fundamental processes due to the agency of soil bacteria, the author found that denitrification goes on under aerobic and anaerobic conditions, being little affected by either. Denitrification proceeds better in solutions than in soils, nitrogen being lost in the greenhouse type of soil used but not in either a silt loam or a clay hillside soil.

Depression of the freezing point in triturated plant tissues and the magnitude of this depression as related to soil moisture, R. P. Hibbard and O. E. Harrington (*Physiol. Researches*, 1 (1916), No. 10, pp. 441-458).—This paper deals with the freezing-point lowering that characterizes the pulpy mass formed by grinding plant tissues, and presents evidence that this lowering is as valuable a criterion for comparing osmotic concentrations of the tissues as is the corresponding index for the expressed juice. The material was first subjected to a preliminary freezing, to render the cell membranes more readily permeable to dissolved materials, after which it was thoroughly triturated. The pulp thus prepared was placed in the cryoscopic apparatus and its freezing-point depression determined just as is usually done with the sap expressed from such pulps. Beckmann's freezing point apparatus was employed.

It was found that this method of testing the pulp without pressing gave concordant results when different samples of the same pulp were tested. In a series of duplicate tests the greatest plus or minus variation between two lowerings that one might expect to be alike was only 0.5 per cent; usually it was less than this. Comparisons of the depressions obtained from tests of plant pulps with those from tests of the expressed juices of the same pulps showed that the two values obtained in these two ways were practically identical, providing that the process of pressing had been very thorough. The agreement was usually within much less than 1 per cent.

The materials employed in these tests were potato tubers, cabbage leaves (from the head), apples, lemons, oranges, grapefruit, onion bulbs, and the tops and roots of maize plants grown in pot cultures. In the case of the maize plants the pots were furnished with autoirrigators, so arranged that six different degrees of soil moisture were practically maintained, in as many different cultures. It was found that the triturated tops showed depressions of from 1.835° C. (culture with mean soil moisture of 31 per cent on dry weight) to 2.204° (culture with soil moisture of 11 per cent), and that the ground roots showed corresponding depressions of from 0.492 to 0.995°. The root material thus had a much lower depression (and consequently a much lower osmotic concentration) than the top material. The depression of the freezing point was found to increase, for both tops and roots, as the moisture content of the soil in which the plants grew decreased, from culture to culture in the series. The order of magnitudes was the same for both roots and tops, being the reverse of the order for soil moisture content.

A list of 27 references to literature bearing on the subject is appended together with an author index.

Glandular hairs on roots, G. Habeblandt (Sitzber. K. Prouss. Akad. Wiss., 1915, XII, pp. 222-226, figs. 6).—The author gives a preliminary report of the occurrence, structure, etc., of multicellular glandular hairs. These were discovered to exist in greater or less abundance on nearly all the rootlets from 2 to 8 mm. in length, springing, with adventitious buds, from marginal leaf notches of Bryophyllum calycinum kept in a glass in the laboratory. The various forms are described and discussed.

Absorption of nutrients as affected by the number of roots supplied with the nutrient, P. L. Gile and J. O. Carreno (U. S. Dept. Agr., Jour. Agr. Research, 9 (1917), No. 3, pp. 78-95, figs. 2).—In a contribution from the Porto Rico Experiment Station, the authors give a report on tests conducted in water cultures to see whether a plant could absorb a maximum amount of one mineral element which was supplied to only part of the roots if all other essential elements were supplied to all the roots. The plants were grown with their roots divided between two flasks, one of which contained a complete nutrient solution and the other a nutrient solution lacking one element, and the absorption of nitrogen with rice and corn and of phosphorus, potassium, and iron with rice was tested.

The results show that, under the conditions of the experiments, the plant is not able to absorb a maximum amount of the element, and the fewer the number of roots supplied with the element, the smaller the amount absorbed. This is found to apply when the total amount of the element supplied is equal to or in excess of the needs of the plant. With nitrogen and phosphorus, the total amount of the element absorbed by plants with half their roots in the complete solution was equal to 0.76 of that absorbed by plants with all their roots in a complete solution. The similar figure for potassium and iron was 0.66. An increase in concentration of the element in question in the complete solution did not appreciably alter the results. The amount of the element absorbed per gram of roots increased greatly as the number of roots in the complete solution was diminished.

Attention is called to the bearing of these results on the method of applying fertilizers.

The excretion of acids by roots, A. R. Haas (*Proc. Nat. Acad. Sci.*, 2 (1916), No. 10, pp. 561-566).—Controlled experiments with sweet corn seedlings grown in water culture indicated that no acids other than carbon dioxid were excreted by the roots. The increase in the alkalinity shown by one culture in quartz in seven days is thought to indicate the presence of some dead cells not visible. Distilled water into which only the roots of wheat seedlings extended showed a very slight increase in alkalinity when the roots had decayed, but when the screen, seeds, and roots were in water a slightly greater increase in alkalinity was noticed.

Leaf epidermis and light perception, G. HABERLANDT (Sitzber. K. Preuss. Akad. Wiss., 1916, XXXII, pp. 672-687).—This is mainly a discussion of contributions by other investigators as bearing upon the author's theory regarding the sensitivity to light of foliar organs. According to this view, structural peculiarities in the cells near the upper side of the leaf cause differences in illumination, and thus serve as a means of detecting the direction of the incidental light ray.

The chemical organization of the assimilatory apparatus, R. Willstätter and A. Stoll (Sitzber. K. Preuss. Akad. Wiss., 1915, XX, pp. 322-346, fig. 1).—Several series of tests with flowers having foliage of different colors are de-

tailed. The fact that assimilation supposedly requires the presence of both chlorophyll and an enzym is considered to indicate that these factors work together in that process. Chlorophyll supposedly forms a dissociable compound with carbon dioxid. The absorption capacity of green, dry, and powdered leaves for carbon dioxid was studied under different conditions and the results are described. It is considered possible that carbamino compounds may be formed from amino or albuminous compounds. The absorbing substance is supposed to act as an accumulator effecting, or favoring, condensation of carbon dioxid.

Assimilation of organic nitrogen by Zea mays and the influence of Bacillus subtilis on such assimilation, R. O. Brigham (Soil Sci., 3 (1917), No. 2, pp. 155-195, pls. 2, figs. 2).—This work was carried out in order to ascertain whether higher plants can utilize organic nitrogen directly without the agency of micro-organisms, to determine the relative importance of the compounds used, and to show how the utilization of organic compounds by plants is affected by the action of a bacterium known to be able to decompose such compounds with the production of ammonia. The work includes experiments on the influence of different nitrogenous compounds, in sterile or inoculated cultures, upon the growth of seedlings of two varieties of Indian corn.

It is stated that *Z. mays* uses asparagin, casein, cottonseed meal, hemoglobin, linseed meal, uric acid, peptone, guanin, alanin, urea, creatin, malt, and glycocoll, these organic nitrogenous substances being named in order of their availability. Guanidin carbonate, guanidin nitrate, diphenylamin, caffein, and benzamid are unfavorable to the growth of *Z. mays*. Guanin is toxic to popcorn but not to dent corn.

Organic substances found to be directly available, but to produce better growth when acted upon by *B. subtilis* were peptone, guanin, alanin, linseed meal, cottonseed meal, casein, hemoglobin, and urea, the last showing this effect only with popcorn. The action of *B. subtilis* did not increase the availability of urea (by dent corn), sodium nitrate, asparagin, ammonium sulphate, uric acid, malt, creatin, glycocoll, and those compounds which were toxic.

Substances found to be better than sodium nitrate in case of dent corn were cottonseed meal, linseed meal, casein, hemoglobin, uric acid, and asparagin. Urea, peptone, guanin, alanin, and creatin, though available, were not better than sodium nitrate. Guanin was toxic to popcorn but available to dent corn. The compounds of the benzene ring were found to be exceedingly toxic to the plants tested.

Ammonium sulphate is said to be a far better source of nitrogen for dent corn than is sodium nitrate, being surpassed only by casein and asparagin. Generally speaking, organic compounds of high complexity are better after ammonification, those of low complexity not being improved thereby. It is thought that nitrification following ammonification would be detrimental. The simpler method of measuring growth by length of leaves gave results very nearly parallel to those obtained by determining the dry weight.

The catalytic action of potassium nitrate in the alcoholic fermentation produced by Sterigmatocystis nigra, M. Molliard (Compt. Rend. Acad. Sci. [Paris], 163 (1916), No. 20, pp. 570-572).—Alcoholic fermentation ascribed to S. nigra in a nutritive solution, following a 0.2 per cent addition of potassium nitrate, was 3.3 times as active as that produced by the addition of the same quantity of ammonium chlorid. The optimum for the former solution was reached at a concentration of 0.4 per cent, as contrasted with a concentration of approximately 5 per cent required for the optimum fermentation with yeast which has been reported by some other investigators.

Stimulation and injury to plants by acids, I. Onodera (Ber. That Inst. Landw. Forsch., 1 (1916), No. 1, pp. 53-110, pls. 2).—Having made a study of the effects of acids on the germination and growth of several cereals and legumes, the results of which are tabulated, the author states that lactic acid is almost harmless to growth. Formic acid stimulates germination in barley, but hinders growth in rice and clover. The effects of hydrochloric acid were decided, but it was surpassed, as regards root injury, by butyric acid. Nitric acid was generally less injurious than the other acids tested, favoring considerably, in dilute concentrations, both germination and growth in rice. Hydrochloric and sulphuric acids strongly stimulated germination and growth, but tended to kill the seedlings eventually.

Acids in moderate concentrations generally tend to produce stimulation, also hastening the attainment of maturity in the plant. Longitudinal growth is more particularly encouraged by acids than is growth in thickness. The increase of growth of plants in dilute acids generally continues longer in the leaves than in the roots.

The various acids are classified according to their injurious effects on plants.

Frost and alterations in leaves of trees, G. Arnaud (Bul. Soc. Path. Veg. France, 1 (1914), No. 1, pp. 21-25, figs. 2).—A study was made of a leaf injury of chestnuts in Paris, which had been ascribed to the influence of tar. The author considers it due to cold weather in spring, in some cases accompanying or conditioning attacks of certain fungi on the leaves.

Effect of environmental conditions upon the number of leaves and the character of the inflorescence of tobacco plants, H. A. Allard (Amer. Jour. Bot., 3 (1916), No. 9, pp. 493-501, pls. 4).—In a study of very severely stunted tobacco plants it was found that the average number of nodes produced above the cotyledons, exclusive of the branches of the terminal whorl, remained constant under all conditions, but that the size of the inflorescence was reduced by unfavorable conditions. Extreme stunting may result in suppression of the branches of the terminal whorl, the inflorescence being reduced to the terminal bloom.

The shedding of flower buds in cotton, S. C. Harland (West Indian Bul., 16 (1916), No. 1, pp. 72-78).—The author has studied the shedding of buds by cotton to test the truth of the statement that if West Indian native cottons be sown out of season they will refuse to bloom until the proper flowering time, November to May.

It is stated that West Indian native and Seredo cottons from Brazil exhibited periodicity, normally producing no flowers during a period extending roughly from June to September. Such types as upland and Sea Island showed no such periodicity.

Shedding was not greatly influenced by root conditions or rainfall. It was shown by the F<sub>1</sub> generation of a cross between Sea Island and West Indian native cotton, the presence of the habit being thus dominant to its absence in this cross. The F<sub>1</sub> progeny of upland and West Indian native cotton did not shed their buds, the absence of the habit being dominant in this case.

A correlation is suggested between resistance to cotton leaf blister-mite (Eriophyes gossypii) and periodicity in flowering.

On the genetics of crinkled dwarf rogues in Sea Island cotton, I, S. C. HABLAND (West Indian Bul., 16 (1916), No. 1, pp. 82-84, fig. 1).—The author noticed in 1915 in a plat of Sea Island cotton made up of the progeny of single plant selections since 1910, certain rogue plants showing reduction in size of all the vegetative parts and in the seed weight, also crinkling, mosaic, and raggedness of edges in the leaves, extreme development of the sympodial habit,

and a tendency to excessive boll shedding amounting to complete sterility in some plants. He has succeeded in growing a few plants from self-fertilized seeds, all of which proved to be rogues, while in case of seeds not self-fertilized the majority of the plants were rogues.

A large number of crosses were made between rogues and Sea Island cotton, the characters of the latter being completely dominant to those of the former. Later, one of the rogues threw off some of the rogue characters. It is thought that the rogue may be considered as a retrogressive mutation due to the loss of a single factor, the deficiency in the proportion of rogues being explained as due to their weakness and liability to early attack by angular leaf spot disease and by mole crickets. Further work in this connection is considered necessary.

On the partial sterility of Nicotiana hybrids made with N. sylvestris as a parent, II, T. H. Goodspeed and A. H. Ayres (Univ. Cal. Pubs. Bot., 5 (1916), No. 9, pp. 273-292, pl. 1).—Having continued the investigations previously noted (E. S. R. 29, p. 320), the authors state that the F<sub>1</sub> hybrids between N. tabacum varieties and N. sylvestris produce very little pollen of normal appearance, while the anther cells show, almost exclusively, shriveled, functionless grains. The apparently normal F<sub>1</sub> pollen did not germinate in its own stigmatic secretion, in that of the parents, or in any one of a great variety of artificial germinating fluids. The pollen of the parents germinated readily in the stigmatic secretion of the F<sub>1</sub> flowers.

The evidence is considered to oppose the view that specific chemical substances play an important rôle in determining whether or not pollen will germinate, and certain results of tests made on germination and growth reaction are deemed to be the effect of the reagents upon the swelling of cell colloids. The absciss-layer formation is the cause of the fall of flower and fruit, and the stimulus thereto is nonfertilization. Fall of flowers and fruits can be retarded by lowering the total concentration of available mineral materials or nutrients, variations in individual constituents being ineffective.

A few normally matured ovules capable of fertilization are produced in  $F_1$  flowers, and a little viable seed is formed after pollination with the normal pollen of the parents. Back crosses are difficult to make in the field, but plants under conditions of low nutrition retained their flowers longer and back crosses were usually successful, though no increase of fertilizable ovules resulted from this more favorable condition for successful back crossing. Grafts between the  $F_1$  hybrid and its parent N. tabacum macrophylla resulted in pollen similar to that from the same plants grown on their own roots, but the flowers and fruits were better retained in the former case.

On the partial sterility of Nicotiana hybrids made with N. sylvestris as a parent, III, T. H. Goodspeed and J. N. Kendall (Univ. Cal. Pubs. Bot., 5 (1916), No. 10, pp. 293-299).—Continuing the work noted above, the present paper gives the results of experiments to ascertain the mode of abscission of flowers and fruits on the F<sub>1</sub> species of Nicotiana hybrids. These studies are considered to yield further evidence regarding the relation between successful pollination and fertilization on the one hand, and abscission of flowers and fruits on the other. The general problem and the literature of abscission are to be dealt with later in a more extended discussion.

It is stated that in *N. tabacum*, *N. sylvestris*, and other hybrids, also in *N. langsdorffii*, the abscisson zone is to be found at the base of the pedicel. A conspicuous grooved ridge, or ring, of tissue stands out around the base of the pedicel in Nicotiana species, which may indicate the position of motor tissue or of a node. The position of the absciss-layer is independent of this groove, being usually distant from it 5 to 7 cell layers. Abscission appears to take place in any portion of the abscission zone distal to the groove, starting in the

cortical tissues just beneath the epidermis on the ventral side and extending around the cortex. There is neither indication of cell division in the tissue involved nor evidence of alteration of cell walls by dissolution of the middle lamellæ or elongation and softening of the entire wall. The separation of the cells appears to be due mainly to increased turgor. Contact may persist until some mechanical agency, as a slight shaking or tapping, breaks the epidermis and the few tracheal elements which may remain intact. The number of cells actually concerned in the process of abscission is greater in the hybrids mentioned than in the parental species, and the same is true of automatic as contrasted with spontaneous abscission.

# FIELD CROPS.

[Report of field crops work at the Minnesota Station] (Minnesota Sta. Rpt. 1916, pp. 38-42).—Additional data on the cost of tobacco growing are reported. The estimated cost per acre was \$36.53, as compared with \$24.25 previously reported, due chiefly to adverse weather conditions necessitating extra hand labor. The yield averaged 1,280.51 lbs. per acre, selling at an average price of 7.5 cts. per pound, and graded as filler.

Selection tests are reported with winter and spring wheat and with oats, as well as cultural studies with alfalfa, Sudan grass, and sweet clover.

The results of crop rotation experiments show increased yields of 13.7 per cent for corn, 14.95 per cent for oats, and 30.98 per cent for wheat, secured in a 4-year rotation of oats, wheat, clover, and corn, as compared with continuous cropping. In the same rotation increases in net gains per acre, as compared with continuous cropping, were for corn 21.4 per cent and for wheat 72.3 per cent.

Corn yields on land plowed in the fall and early spring were practically equal. The growing of oats and the securing of a stand of clover and timothy on spring-plowed land was not so satisfactory as on fall-plowed land or on double-disked corn land.

[Report of field crops work at the Crookston substation] (Minnesota Sta., Rpt. Crookston Substa., 1910-1916, pp. 27-70, 81, 82).—Cultural, variety, fertilizer, and rotation tests are reported, together with brief notes on corn-breeding work and methods of weed eradication.

Rate-of-seeding tests have been conducted with corn, oats, barley, spring and winter wheat, and winter rye. The winter cereals have not proved satisfactory, owing to excessive winterkilling, while tests with spring-sown grain have failed to give conclusive results and will be continued.

Tests of different methods for protecting winter wheat were begun in 1911 but failed to give very satisfactory results until 1916. Wheat sown on corn left uncut yielded 43.5 bu. in 1912 and 32.1 bu. in 1916. Wheat sown on corn stubble and covered with 1 ton of straw per acre yielded 28.8 bu. in 1916. The tests with straw covering are to be continued.

Trials of seeding alfalfa and red and sweet clover with wheat and oats at different rates as nurse crops, and with no nurse crop, were begun in 1915. With a nurse crop, in 1915, a stand of 60 per cent and low vigor resulted without any apparent difference between the rates of seeding, while without a nurse crop, a 100 per cent stand and excellent vigor were secured. The 1916 results were rather contradictory, due to the relatively short and less rank growth of the nurse crops. Field tests with alfalfa to determine the relative importance of various factors in their influence upon the growth of the crop indicated that they rank as follows: No nurse crop, manure, inoculation, and lime.

Other cultural projects which are briefly noted include tests of subsoiling, deep plowing, and packing the seed bed, a comparison of tractor and horse plowing and disking, date of plowing, and disking stubble tests. Final conclusions are not yet drawn.

In variety tests with oats, 1911-1916, the seven highest-yielding varieties, Danish Trifolium, King Oscar, Improved American, Canadian 429, Golden Beauty, Swedish Victory, and Early Everett averaged over 55 bu. per acre. Early Champion, Kischener, Big Four, New Zealand, and Swedish Select, the five lowest-yielding varieties, averaged under 45 bu. per acre.

Swanhals barley, with an average yield of 40.1 bu., was first of the tworowed types, with Gutecon lowest with a yield of 24.6 bu. The highest-yielding six-rowed type was a Russian variety, which yielded 44 bu. per acre, with the lowest yield from Eagle No. 913, 21.82 bu.

With wheat, the three highest-yielding varieties, Minnesota No. 951, Marquis, and Kubanka, averaged over 24 bu. per acre. The four lowest-yielding varieties, Minnesota No. 169, Rysting, Powers, and Eames, averaged from 15 to 18 bu.

Field tests with millet, field peas, soy beans, clover, and alfalfa have continued for a period of 20 years to determine the adaptability of these crops to northwestern Minnesota. Variety tests were begun in 1913. The highest yield of forage was secured from Early Amber cane, 10,757 lbs. per acre, in 1916, with Sudan grass second with a yield of 7,454 lbs. Southern German millet gave a four-year average yield of 7,394.25 lbs. Blue Scotch No. 1436 field pea gave the highest average yield, 13 bu., of the varieties tested.

In 1915, 12 varieties of grasses, 4 of legumes, and 7 combinations of grasses and legumes were seeded separately and harvested for the first time in 1916. Of the grasses sown alone, the highest yield was secured from meadow fescue, 6,780 lbs. per acre. Sweet clover, with a yield of 6,380 lbs., was highest for the legumes. The highest yielding combination consisted of 10 lbs. *Bromus inermis*, 6 lbs. tall meadow oat grass, 2 lbs. white clover, and 4 lbs. alfalfa, and gave a yield of 6,660 lbs. per acre.

In corn variety tests, Northwestern Dent gave the highest grain yields for the two years reported, 1914 and 1916, with 46.87 and 38.4 bu., respectively.

Tests with flax for fiber, conducted in cooperation with the Office of Fiber Investigations, U. S. Department of Agriculture, in an effort to develop strains of fiber flax adapted to northwestern Minnesota, are reported. Hemp has been successfully grown for fiber at the station.

The following are the highest average yields per acre secured in crop-rotation tests from 1911 to 1916, inclusive: Wheat, 22.84 bu. in the three-year rotation, with a yield of 16.25 bu. for continuous wheat; oats, 57.7 bu. for the seven-year rotation, with a yield of 53.8 bu. for oats grown continuously (two-year average); barley, 43.3 bu. for continuous barley (two-year average) and 39.03 bu. for the seven-year rotation; flax, 15.73 bu. in the seven-year rotation; corn, 39.83 bu. in the seven-year rotation, with a yield of 34.33 bu. when grown continuously; potatoes, 98.2 bu. in the four-year rotation (two-year average) without manure, fertilizer, or legume; and hay, first year, 4,765 lbs. in the seven-year rotation, and second year, 1,918 lbs. in the five-year rotation.

Data are presented showing the results of commercial fertilizer tests with and without manure for crops grown in rotation for 1914, 1915, and 1916. No definite conclusions have been drawn.

Eradication of quack grass has been accomplished through severe bare fallow, followed by corn.

A number of potato variety tests are reported. Early Ohio is deemed the best market variety for this region, while Irish Cobbler is a high yielder and

the best early white potato tested. Carmen No. 1, Green Mountain, and Carmen No. 3 are considered the best late varieties. In cultural tests to determine the size of seed pieces, the double eye and quarter sizes have given the highest yields per pound of seed. A planting rate of 16 bu. per acre gave an average yield of 140.25 bu. as compared with a yield of 78.26 bu. from a 10-bu. planting rate. Hill-selected seed gave an average yield of 184.92 bu. per acre, as compared with a yield of 134 bu. from cellar-selected seed, 64.75 bu. from field run, 88.72 bu. from run-out seed, 136.15 bu. from tuber-unit selection, 75.4 from little field-run stock, and 144.6 bu. from little-selected stock. Tests with various treatments for seed potatoes and spraying tests for tuber and leaf diseases and insect pests are also reported.

Twenty-four varieties of rutabagas, mangels, carrots, and stock turnips have been tested. The highest-yielding varieties were the White Half Sugar mangels, 24.86 tons; Sweet Russian rutabagas, 488.6 bu.; Cowhorn turnip, 504 bu.; and Mastodon carrots, 355 bu. per acre.

[Report of field crops work at the Crookston substation] (Minnesota Sta. Rpt. 1916, pp. 68-70, 72).—Field crops work for 1915, as noted above, is briefly reviewed.

[Report of field crops work at the Duluth substation] (Minnesota Sta., Rpt. Duluth Substa., 1916, pp. 5, 6, 7, 9; abs. in Minnesota Sta. Rpt. 1916, pp. 79, 80).—In variety tests the average oat yield for the season was 42.5 bu. per acre and the time required for maturity from 93 days for Sixty Day oats to 113 days for the White Russian side oats. The early-maturing strains are considered the best yielders. The average barley yield was 20 bu. per acre, with Minnesota No. 105, a 6-rowed variety, highest. The 2-rowed barley, Princess, required 93 days to ripen, while all others required 87 days. The Alaska variety of peas is recommended because of its early maturity (84 days). Minnesota No. 95 required 112 days. Twenty-two varieties of corn were tested, the following giving the most promise for fodder: Minnesota No. 13, Northwestern Dent, Longfellow, and King Philip Flint.

Flax sown June 1 matured in 101 days. Rutabagas planted in May were harvested the middle of October, little difference being noted between three standard varieties.

Fertilizer tests under a 3-year rotation plan, using rock phosphate manure and acid phosphate, are reported. The crops grown were potatoes and rutabagas.

Three methods of seeding grass on cut-over land were compared. Harrowing with a spring-toothed harrow before and after seeding proved more satisfactory than harrowing before seeding, and this in turn was superior to harrowing after seeding.

[Report of field crops work at the Grand Rapids substation (Minnesota Sta. Rpt. 1916, pp. 75, 76, 77).—The crop yields secured in 1915 and the projects in progress are briefly noted.

The average yield for all oats was 76.9 bu. and the average of 13 varieties, 91.7 bu., with Sixty Day highest with 110.6 bu. The wheat average was 26.9 bu. per acre. The average of 13 varieties was 26.6 bu., with Prelude highest with 30.6 bu., followed by Marquis with 30.5 bu., and Haynes Bluestem with 30.3 bu.

The average barley yield was 42.6 bu. per acre, with an average for 10 varieties of 54.6 bu. O. A. C. No. 21 gave the highest yield, 63.9 bu. for the 6-rowed varieties, and Champion of Vermont, 55.6 bu. for the 2-rowed varieties.

Average yields were secured of corn for silage 3.4 tons; potatoes, 136.6 bu.; clover and timothy (first cutting), 2.42 tons; and rutabagas (topped), 24.47 tons per acre. Potato trials indicated homegrown seed to be superior to im-

ported seed. Meadow fescue showed promise as a grass crop for either hay or pasture on muskeg.

[Report of field crops work at the Morris substation] (Minnesota Sta., Rpt. Morris Substa., 1915, pp. 5-12, figs. 3; abs. in Minnesota Sta. Rpt. 1916, pp. 73, 74).—Field experiments at the West Central substation at Morris for 1915 were confined to crop rotations, fertilizer tests, and variety and seeding trials with the farm crops common to western Minnesota.

A four-year rotation of corn, wheat, oats, and clover is being grown with 18 plats in each crop each year. These plats receive six different treatments, including no fertilizer, rock phosphate alone, acid phosphate alone, manure alone, rock phosphate with manure, and acid phosphate with manure. Two seasons' crops have been harvested and the results tabulated, but thus far have not shown sufficiently increased yields over the untreated plats to pay the cost of applying the fertilizer.

Yields of 21 strains and varieties of alfalfa being tested in nursery rows are reported. The Grimm, Baltic, and Imported Turkestan varieties appear to be sufficiently hardy to withstand the winters of this locality.

Alsike clover has proved satisfactory on wet lands.

Yields of 9 varieties of corn tested which failed to mature fully, 7 varieties of spring wheat tested for rust resistance, and 3 varieties of barley damaged by storms, are reported.

Of 7 varieties of oats tested the yields varied from 64.2 to 100.5 bu. per acre. Improved Ligowa gave the highest yield with the least lodging. Marrowfat peas yielded 24.3 bu. per acre, as compared with 9.5 bu. from Early Alaska.

[The Woburn field experiments, 1915], J. A. VOELCKER (Woburn Expt. Sta. Rpt., 1915, pp. 1-15, 20-29; Jour. Roy. Agr. Soc. England, 76 (1915), pp. 317-330, 334-344).—In continuation of work previously reported (E. S. R., 35, p. 30), this deals with the season of 1915, which was marked by heavy rainfall during the winter and a prolonged drought\*in the summer.

In the wheat experiments the plat receiving farmyard manure gave the highest yield, 24.4 bu. per acre, together with the most straw. The plat receiving rape dust gave the second highest yield, 23.2 bu., while the average of the two unfertilized plats was 12.9 bu. With mineral manures alone the yield was about 1 bu. less per acre than on the unmanured plats, but there was rather more straw. Ammonium sulphate used alone was unsuccessful, but upon the addition of lime increased yields were obtained. Nitrate of soda showed, on the whole, better results than sulphate of ammonia, probably due to the dry season. The use of phosphates produced 1 bu. more per acre than the use of potassium sulphate. The highest quality of wheat was obtained from the nitrate of soda plats, that from the farmyard manure plat being graded as only moderate.

In order to determine whether flax is a soil-exhausting crop wheat was sown on two adjoining fields, from one of which flax and the other oats had just been removed. The yield after flax was just double that after oats.

In the barley experiments, determinations showed a higher moisture content on the nitrate of soda plats than on the ammonium sulphate plats. The highest barley yield, 27.3 bu., was obtained from the plat receiving farmyard manure, while the plat receiving mineral manures and 1 ton of lime in 1915 was second, with 19.1 bu. The average for the untreated plats was 10.2 bu. The use of ammonium sulphate alone gave no crop, and when used with lime inferior yields were obtained, but when mineral manures were added an increased yield resulted. Sodium nitrate alone gave poor results, although increased yields were obtained when used in conjunction with mineral manures.

The yield was smaller by 2.2 bu. per acre after the use of potash than with phosphates, and the quality of the barley was reported as poor. Variety tests with barley were continued, Chevalier yielding 13 bu. more than Tystofte and 19 bu. more than Svalöf, but its quality being inferior to that of the other two.

Rotation experiments to study the unexhausted manurial value of grain (barley, oats, and chaff) and cake (linseed cake, cottonseed cake, and chaff), when fed to sheep as a supplement to the roots in the rotation, showed tentatively that the corn-fed plat gave slightly higher yields in the subsequent crops.

Tests were continued with clover and grass mixtures, the best yields of hay being obtained from a mixture including "wild" white clover. Variety tests with alfalfa laid down in 1911 show the best results with Russian (Europe) and with Province second.

Mangels were grown beside sugar-beet plats, and it was observed that the beets required approximately three times the labor that the mangels did in harvesting. It was also ascertained that, due to the large amount of earth retained, the beets lost 32 per cent in washing, while the mangels lost only 9 per cent.

In pasture improvement the farmyard manure plat gave the highest returns, but was inferior in quality, while the plat receiving 10 cwt. of basic slag and 1 cwt. of potassium sulphate gave the best all-round results. In testing the varieties of lime best for grassland, Buxton lime showed the highest yield. Lump lime and ground chalk gave better results than ground lime and ground limestone.

In tests instituted in 1913, plats alternately mown and grazed gave the highest yields of hay and left an aftermath of superior quality.

Cultivation and utilization of sunflower, niger, and safflower seed (Bul. Imp. Inst. [So. Kensington], 14 (1916), No. 1, pp. 88-101).—Brief notes are given on the cultivation, harvesting, and utilization of the seed of sunflower (Helianthus annuus), niger-seed plant (Guizotia abyssinica), and safflower (Carthamus tinctorius) in South Africa.

The entire sunflower plant produces silage of fair quality. The stalks alone are often used for fuel and the ash, which is high in potash, as a fertilizer. The seed of all three plants is used for oil extraction, and the seed cake resulting as a concentrate.

Pasture problems.—Indigenous plants in relation to habitat and sown species, R. G. Stapleton and T. J. Jenkin (Jour. Agr. Sci. [England], 8 (1916), No. 1, pp. 26-64).—This paper continues work previously noted (E. S. R., 33, p. 227), and attempts to trace (1) the relationship that exists between the several indigenous plants that contribute to the herbage of definite types of grassland, (2) the progressive changes that occur on fields, down to grass for a varying number of years, belonging to these types, (3) the competitive interaction between sown and indigenous species, and (4) the contrast in effect on the herbage of continual mowing and continual grazing.

The types of grassland investigated are divided into two groups, the natural and the seminatural. By natural types are meant those pastures which historical evidence shows never to have been extensively under the plow or manured and which, if broken or manured at some remote period, have completely reverted to type. By seminatural types are meant those pastures which of certainty have been under the plow and, at all events, manured during the rotation previous to reverting to grass. The seminatural types are further classified as the tended and untended. The tended are those pastures which have been down to grass about 20 to 50 years, receiving periodic if but slight dressings of manure and probably sown in the first instance with rye grasses and clovers only

or with loft sweepings. The untended are those which have been plowed and probably manured from 50 to 100 years ago and then, after yielding crops for some seasons, allowed to revert to grass without any sowing (with the possible exception of loft sweepings) and have so remained ever since without any further manuring in most cases.

Plants which colonize natural grasslands are called primary indigenous species, and those which come in without being sown and contribute largely to the herbage on seminatural grasslands are designated as secondary indigenous species. Plants that come in alone but which disappear as the field approaches the seminatural are called tertiary indigenous species, and are to be dealt with in a subsequent paper. Plants which are indigenous in a district but do not contribute to the flora of a well-marked type of grassland are called locally exotic, and those not indigenous in a district exotic. These classifications and distinctions are deemed applicable to all districts and type of grasslands.

Considerable space is devoted to a discussion of the composition of the herbage on the various pasture lands observed and on the stabilization of grasslands. The behavior of the chief plants found on all the types of grassland studied is also discussed under a separate heading for each individual species. The general conclusions may be summarized as follows:

The number of primary species on most types is not considerable and they are usually late in making their appearance in fields put down to grass after a long period of rotation. Primary species which come in early are frequently weeds of arable land, such as *Poa trivialis*, *Festuca rubra*, and *Agrostis vulgaris*.

As regards the relation of primary and secondary species to their commercial and sown counterparts, commercial seed may not appreciably hasten the appearance or add to the quantity of the desired plant. This is especially true of the fine-leaved fescues and even of *Trifolium repens*. Phosphatic manures often prove to be sufficient to hasten the appearance of the indigenous plants.

Commercial seed may produce a great bulk of the required plant and only after several years will the plant attain its normal development, indicating that the final plant is the indigenous counterpart of the sown species. Commercial seeding is ecnomically justified in such cases. Commercial seed may also hasten the appearance of the desired species, but there is a risk of the sown plant interfering with the development of the definitely lasting indigenous species; this is more a matter of local importance. The spontaneous appearance of primary and secondary species on land long under rotation when put down to grass may be due to the following: (a) Many species remain as arable weeds; (b) the seeds of many species may be wind borne; (c) seeds may be introduced as impurities in sown seed; and (d) the seeds of a great many species are evidently capable of lying dormant in the soil for long periods.

In addition to the conclusions given above, certain generalizations are presented regarding experimental work on grassland and the whole problem and economics of putting land down to grass. A bibliography of 20 references is given at the end of the paper.

Observations on alfalfa, E. H. Jenkins (Connecticut State Sta. Bul. 192 (1917), pp. 12).—Limited observations of four years of alfalfa growing with the Grimm, Sand Lucerne, Kansas-grown, Provence, Utah-grown, and Turkestan strains are briefly noted. Grimm gave the highest average yield for the 4-year period, 4.39 tons per acre, on limed soil. The lowest average yield, 3.4 tons, was secured from the Turkestan variety. These two varieties suffered least from winterkilling, while the Sand Lucerne and Provence suffered slightly, and the Utah- and Kansas-grown strains the most.

The determined cost of plowing, seed bed preparation, liming, and fertilizing (basic slag, acid phosphate, and muriate of potash) amounted to \$53.91 per

acre. The estimated cost of seeding and inoculating, spreading fertilizer, and cutting, curing, and hauling the crop (4 tons per year for four years, at \$2 per ton) brought the total cost of production for four years to \$95.91 per acre.

Beans in Colorado, A. Kezer (Colorado Sta. Bul. 226 (1917), pp. 3-20, figs. 6).—Detailed directions are given for preparing the seed bed, planting, cultivating, harvesting, threshing, and marketing the bean crop in Colorado. It is estimated that the acreage planted to beans increased 81 per cent in 1916 over that planted in 1914 and 1915, and that the total yield increased 41 per cent in the same period.

It is stated that Pinto beans, the chief Colorado market variety, average from 300 to 800 lbs. per acre under dry-farming conditions and may yield 1,800 lbs. Under irrigation this variety will average from 1,200 to 2,000 lbs. and may yield 3,000 lbs. or more. The bean straw will average on dry land from one-half to three-quarters ton per acre.

Systematic rotation of beans is urged as a disease-control measure. Wheat following beans on dry land is reported as yielding as well as after the usual summer fallow in most seasons.

The cost of bean production on dry land has been found to average from \$5 to \$8 per acre and on irrigated land from \$9 to \$15. These estimates are exclusive of machinery costs, interest on land, cost of irrigation, ditch upkeep, and rentals.

Clover and clover hay, A. and GABRIELLE L. C. HOWARD (Agr. Jour. India, 11 (1916), No. 1, pp. 71-78).—Notes are given on the value and production of Persian clover or shaftal (Trifolium resupinatum) in the Quetta Valley, India. Its adaptability to local conditions and the excellent quality of hay obtained under arid conditions have contributed largely to its successful production.

Corn problems.—Choice of varieties; time, manner, and rate of planting, C. A. Gearhart (Mo. Bul. Ohio Sta., 2 (1917), No. 4, pp. 104-109, figs. 5).—Brief recommendations are made regarding the choice of varieties and the time, manner, and rate of planting corn.

In date-of-planting tests at Wooster the periods of May 4 to 10 and May 14 to 17 gave the highest yields, 64.22 and 64.36 bu. per acre, respectively, for an 8-year average, while corn planted April 24 to 29 outyielded that planted May 25 to 28 and June 2 to 6. The last two named planting periods produced 26.15 and 38.36 per cent nubbins, respectively, while the other planting periods were comparatively uniform, giving about 17 per cent nubbins. The early-planted corn was also more mature than that planted later, the moisture content at the time of husking varying from 25.85 per cent for the first planting to 36.4 per cent for the last.

Corn drilled rather than planted in hills, with plants 12 in. apart, gave the highest 3-year average yield of grain, 46.88 bu. per acre, and of stover, 2,827 lbs. It is stated, however, that the methods of cultivation and harvesting will determine to a large extent the method of planting to be employed.

In rate-of-planting tests the yields from the four- and five-plant rates were the highest, 64.34 and 62.6 bu. per acre for an 11-year average, respectively, but with a percentage of nubbins of 30.2 and 41.2, respectively. The three-plant rate was deemed the most satisfactory where corn is to be husked. The yield of the latter was 60.95 bu. of shelled corn per acre, with 21.4 per cent nubbins. Where the crop is to be fed from the shock the thicker rates of planting are preferable.

How much plant food does a corn crop take from an acre? E. H. Jenkins, J. P. Street, and C. D. Hubbell (Connecticut State Sta. Bul. 193 (1917), pp. 11, 12).—From nine series of tests with husking and silage corn at different experiment stations the average amounts of nitrogen, phosphoric acid, and potash

removed by the crop were 87.5, 42, and 67.1 lbs per acre, respectively. Six tests at Mt. Carmel gave for a 15-ton silage crop an average of 88 lbs. of nitrogen, 37 lbs. of phosphoric acid, and 100 lbs. of potash. Several crops of husking corn, grown elsewhere in Connecticut and calculated at 75 bu. per acre, gave an average of 92 lbs. of nitrogen, 34 lbs. of phosphoric acid, and 74 lbs. of potash.

It is estimated that by careful conservation of the manure returned from feeding 30 tons of silage approximately 50 lbs. of nitrogen, from 25 to 30 lbs. of phosphoric acid, and from 45 to 50 lbs. of potash may be regained regardless of any fertilizing ingredients in the litter or fermenting organic matter which might serve as a soil amendment or plant-food solvent.

Corn variety tests for 1915, R. Y. WINTERS, G. M. GARREN, and B. WHITE (Bul. N. C. Dept. Agr., 37 (1916), No. 4, pp. 5-21).—Tests of 24 varieties of corn at six experimental farms in North Carolina are reported and compared with the average results of previous tests.

The 2-eared prolific varieties yielded best, except in the extreme western part of the State, where Boone County White, a 1-eared variety, gave the highest yield in a series of five tests. It is recommended that the best 2-eared varieties be improved by selecting for increased yield of grain per stalk rather than a larger number of ears per stalk. For production of silage the 2-eared and more prolific varieties have given a higher yield of dry matter and more food value per acre than the 1-eared varieties.

Egyptian maize (Zea mays), G. C. Dudgeon and B. G. C. Bolland (Min. Agr. Egypt, Tech. and Sci. Serv. Bul. 9 (1916), pp. 5).—This is a progress report of variety tests with corn at the Gheezeh Experimental Farm in an effort to isolate and describe the varieties grown. Brief notes are also given on the production of the crop in Egypt.

Fique (Furcræa gigantea) (Roy. Bot. Gard. Kew, Bul. Misc. Inform., No. 7 (1916), pp. 169, 170, pl. 1).—This is a brief note on fique in Colombia, including an enumeration by M. T. Dawe of the principal uses to which the fiber is put.

The culture and manufacture of flax for fiber and seed with special reference to the industry in Oregon, J. F. THORNE (Univ. Oreg. Bul., n. ser., 13 (1916), No. 13, pp. 70, figs. 5).—This is a compilation of data and expert opinions on the establishment of the flax industry in Oregon, made by the School of Commerce of the University of Oregon at the request of the Flax Committee of the Portland Chamber of Commerce. It discusses the climatic conditions and advantages of Oregon for flax production, and, in addition, the demand, freights, markets, prices, profits, and conditions of the flax industry in foreign countries.

Indian hemp fiber (Crotalaria juncea), C. D'LIMA (Agr. Jour. India, 11 (1916), No. 1, pp. 31-41).—This is a general discussion of the hemp situation in India from a commercial standpoint.

[The composition of mangels], C. T. GIMINGHAM (Univ. Bristol, Ann. Rpt. Agr. and Hort. Research Sta., 1915, pp. 114-119).—Analyses of six varieties of mangels grown at each of eight experimental centers are reported.

Great millet (Sorghum vulgare) and berseem (Trifolium alexandrinum), B. G. C. Bolland (Min. Agr. Egypt. Tech. and Sci. Serv. Bul. 8 (1916), pp. 5).—A progress report of work conducted with millets in 1915 in an effort to isolate and describe the individual varieties grown at the Gheezeh Experimental Farm. Tests with four strains of berseem are also reported.

Peanuts.—Tests of varieties and fertilizers, J. F. Duggar, E. F. Cauthen, J. T. Williamson, and O. H. Sellers (*Alabama Col. Sta. Bul. 193 (1917)*, pp. 3-32, pls. 4).—Variety tests covering a period of five years and fertilizer tests extending over six years in different parts of the State are reported.

The average yield of unshelled peanuts obtained in the variety tests ranged from 871 lbs. for the McGovern variety to 1,244 lbs. for Red Spanish. The average percentage of shelled nuts varied from 39.3 for Jumbo to 75.1 for White Spanish. The heaviest unshelled peanuts were the Tennessee Red (246 pods to the pound) and the lightest White Spanish (461 pods to the pound). Based on the average percentage of sound nuts and the oil content of each variety, the varieties, arranged according to pounds of oil produced per ton, are as follows: White Spanish 702 lbs., Red Spanish 693, Valencia 572, McGovern 548, Tennessee Red 527, North Carolina Runner 524, Virginia Runner 493, and Jumbo 354 lbs.

Brief directions are given for preparing the seed bed, planting, cultivating, and harvesting the crop. The largest yields were obtained from plantings made between May 1 and June 15.

Chemical analysis of peanut straw showed 10.72 per cent water, 10.69 protein, 1.66 fat, 29.5 crude fiber, 41.39 carbohydrates, 6.03 ash, 1.2 potash, and 0.5 per cent phosphoric acid.

From tests made to study the residual effect of peanuts on the succeeding crops, as compared with corn, it was concluded that the peanut crop harvested in the usual way for seed does not improve the soil for succeeding crops. From complete fertilizer tests it was concluded that acid phosphate at the rate of 200 to 300 lbs. per acre produced profitable increases in yields on sandy and other well-adapted soils. Potash, as kainit, at the rate of 100 and 200 lbs. per acre was not always profitable except on a few infertile, sandy soils. Slacked lime at the rate of 600 lbs. per acre gave profitable increases on sandy soil. Cottonseed meal as a nitrogenous fertilizer was not profitable.

The average yield of peanut straw from four experiments varied from 2,316 lbs. for North Carolina Runner to 1,234 lbs. for Virginia Bunch per acre. The average percentage of dry, unhulled peanuts to the weight of the whole plant ranged from 32 for North Carolina Runner to 39 for Red Spanish.

Growing peanuts in Alabama, J. F. Duggar, E. F. Cauthen, J. T. Williamson, and O. H. Sellers (Alabama Col. Sta. Bul. 194 (1917), pp. 35-48).—A popular edition of the above.

A note on the inheritance of certain stem characters in sorghum, G. R. Hilson (Agr. Jour. India, 11 (1916), No. 2, pp. 150-155, pl. 1).—Observations of some selected strains of sorghum in the Madras Presidency led to the conclusion that all of these strains could be placed in one or the other of two groups, according to the appearance of the midrib of the leaf. One group is composed of all plants in which the midrib appears as an opaque white band running the entire length of the leaf, while the other group includes those plants in which the midrib in the lower leaves is marked by dull white, generally broken bands never extending across the full width of the midrib and rarely to the end of the leaf, while the upper leaves are entirely devoid of any white marking.

Repeated tests have led to the conclusion that a grayish midrib indicates a stem rich in sugar, while a white midrib shows a pithy, insipid stem. With these characteristics in mind a number of breeding experiments were conducted with the following results: (1) The character of the green stem in sorghum can be readily diagnosed from the appearance of the midrib of the leaf, and (2) in breeding tests the pithy, insipid character of the stem behaves as a simple dominant to the sweet-stalked character.

Tests of soy beans in 1916, E. H. Jenkins, J. P. Street, and C. D. Hubbell (Connecticut State Sta. Bul. 193 (1917), pp. 3-10).—Continuing work previously noted (E. S. R., 35, p. 532), the yield and composition of 17 varieties of soy beans are reported. The range in time of maturity in 1916 was from

105 to 127 days; in yield of green forage from 7,362 to 13,590 lbs. per acre, with an average of 9,839 lbs.; in yield of dry matter from 1,992 to 3,325 lbs., with an average of 2,600 lbs.; and in protein from 3.2 to 6.6 per cent, with an average of 4.6 per cent.

Of 12 varieties of soy beans tested for three years the Wilson has produced the highest amount of dry matter per year, 3,329 lbs., with the Mongol variety last, 2,406 lbs. Both varieties required an average of 122 days to attain maturity.

Exclusive of roots the crops of the last three years contained per acre 3,637 lbs. of organic matter, 111 lbs. of nitrogen, 20 lbs. of phosphoric acid, and 79 lbs. of potash.

The Whippoorwill and Brahman varieties of cowpeas were tested, yielding 2,542 and 2,160 lbs. of organic matter and 54 and 50 lbs. of nitrogen per acre, respectively. The average composition of the dry matter of soy beans and cowpeas grown at Mt. Carmel during 1916 is compared in tabular form.

Soy bean growing is briefly discussed and the uses of the crop in Connecticut outlined as follows: Sowing as a catch crop following winterkilled grain or clover or a poor spring seeding, from the first of May to the middle of June; as a late summer soiling crop for cattle; as a silage crop grown either with or without corn and cut into the silo—about 3 tons of corn to one of soy beans; as a green manure; and as a seed crop.

Soy beans.—Their culture and use, C. G. WILLIAMS and J. B. PARK (Ohio Sta. Bul. 312 (1917), pp. 579-600, figs. 4).—Soy-bean production in Ohio is discussed in detail.

In rate-of-seeding tests 3 pk. of medium-sized soy beans (Medium Green variety), sown in rows 28 in. apart, has usually given the best results for seed production. A seeding of 8 pk. per acre drilled solid gave a smaller yield of seed, but a higher yield of total forage.

Twenty-five varieties and pure-line strains are briefly described, and the results of variety tests in yields of grain and straw and the pounds of straw per bushel of grain are reported in tabular form. The five leading varieties in order of rank were: Ohio 9016, Ohio 7496, Elton (Chestnut), Ito San 17268, and Shinto. The five lowest yielders were Sable, Cloud, Yosho, Mikado, and Taha. The yield in grain per acre for the five-year average, 1911–1916, inclusive, varied from 14.01 bu. for the Sable variety to 29.22 bu. for Ohio 9016. The high-yielding varieties showed a low proportion of straw to grain, ranging from 72 to 97 lbs, of straw per bushel of grain, with an average of 81 lbs., whereas in the five low-yielding varieties the range was from 106 to 164 lbs., with an average of 133 lbs. The total average yield of straw, however, in the two classes varied only 177 lbs. per acre.

Results obtained with a few varieties tested at the experimental farms located in Clermont, Hamilton, Washington, Paulding, and Trumbull counties are also reported.

Tests with ten varieties of soy beans for hay have been conducted at Wooster for five years. The Medium Green variety has given the highest average yield, 5,402 lbs. per acre, with the Mammoth Yellow lowest, with 3,814 lbs. Medium Green is deemed better adapted for hay production than for grain because of its tendency to shatter.

Limited observations have been made of the effect of soy beans upon subsequent crops in the rotation. Fifty rotations are in progress, and 24 wheat plats were harvested in 1916. Ten of these plats followed corn, 6 soy beans, 5 potatoes, and 3 oats. The average yield of wheat following soy beans was 10.3 bu. greater than that following corn, 1.27 bu. greater than that following oats, and 0.34 bu. greater than that following potatoes.

The uses of soy beans for human and animal food and for such special products as soy-bean meal and soy-bean oil are discussed. Charts are presented showing the relative value of soy beans and several common food materials.

Sudan grass, B. A. Madson and P. B. Kennedy (California Sta. Bul. 277 (1917), pp. 195-224, figs. 5).—The field practices and cultural methods employed in the production of Sudan grass, both for hay and seed, in California are discussed. Date, rate, and method-of-seeding tests for hay production and method-of-seeding tests for seed production, carried on in cooperation with the U. S. Department of Agriculture, are for 1913, 1914, 1915, and 1916.

The average yield of cured hay varied from 1.8 to 5.9 tons per acre on dry land and 3.9 to 6.7 tons on irrigated land. The average yield of seed is estimated at from 600 to 800 lbs. per acre. For hay production seedings of from 10 to 15 lbs. in rather narrow rows (18 in.) seemed to give the best results, although heavier seedings sown broadcast, drilled, or in wider rows gave good results, depending largely upon the available moisture supply. Seeding should not be done until all danger of frost is passed and the soil has become thoroughly warm. From 75 to 80 days after seeding are required to secure the first cutting, about 45 days more for the second, and 50 days more for the third. A seed crop can be produced in from 95 to 100 days.

Analyses are reported of various hay crops for a comparison with Sudan grass and indicate that due to the large production of dry matter (6,367.7 lbs. per acre for a 3-year average) this crop is superior to the usual cereal and grass hays in the amount of food constituents produced per acre, although it can not compete with alfalfa.

It is recommended that Sudan grass be grown in rotation following a spring crop, such as grain or spring pasture, which could be removed by the first to the middle of July.

The method for distinguishing the seed of Johnson grass and Sudan grass devised by Hillman (E. S. R., 35, p. 834), is noted.

Report of the plant breeder, H. B. Cowgill (Rpt. Bd. Comrs. Agr. P. R., 4 (1914-15), pp. 22-33; 5 (1915-16), pp. 16-20, 21-34).—This reports the continution of work at the Porto Rico Insular Station with sugar cane (E. S. R., 33, p. 532) for the years of 1914-15 and 1915-16.

The propagation of seedling canes and a rigid selection and careful choice of parent varieties has been continued. Several attempts at cross-pollinating cane varieties are reported with a considerable degree of success. The methods employed in 1914–15 included planting a pollen-sterile variety to the leeward of a pollen-fertile variety which blooms at the same time and tying together the tassels of the varieties to be crossed before the florets of either had opened. The pollen-sterile variety used in the first case was the Otaheite and the pollen-fertile parent B 347. In the second case Crystalina (the pollen-sterile parent) and D 109 were the varieties used. Sixteen hundred seedlings were produced by the latter method and 1,745 seedlings obtained from open cross-pollination were planted in the field in 1915–1916. Of the last-named group 80 plants were selected as of superior quality. The results of the crosses and the value of different varieties as parents are discussed.

A list of the cane varieties grown most extensively on the island is given and their relative importance discussed. Striped cane, Otaheite, and Crystalina take rank in the order named with regard to the area occupied by each. The value of numerous imported varieties, as indicated by actual field observations, is also discussed.

Tests of 25 varieties of cane are reported for 1914-15, showing the yields of plant cane and first and second ratoons, with an analysis of the juice for the

first two crops. Seeley Seedling gave the best results, considering the quality of the juices and the weight of the cane produced. Twenty varieties of recently introduced cane were tested for the first time during 1914–15, and the test continued in 1915–16. Among these varieties the most promising were B 1809, B 7245, B 6292, B 3859, B 3405, and B 3747, all giving higher yields than Crystalina or Otaheite, the check varieties.

Thirteen leguminous cover crops were tested in 1914–15, and the results are presented in tabular form with regard to germination of the seed, habit of growth, length of growing season, amount of seed produced, and resistance to insect and disease pests.

The average yield of cane from all unfertilized plats in 1914–15 was 8.17 tons per acre as compared with an average yield of 22.46 tons for the plats receiving a complete fertilizer. The highest yield, 26.6 tons, was secured from the plat receiving 120 lbs. phosphoric acid, 60 lbs. nitrogen, and 60 lbs. potash. These results are in agreement with those obtained in the two previous years, and in general were confirmed in 1915–16, when the highest yield, 20.75 tons, was obtained from a double application of a complete fertilizer. All the fertilizer experiments indicated the need of abundant phosphoric acid applications on these soils,, while potash and nitrogen fertilization is evidently of secondary importance.

Further fertilizer experiments were conducted in 1915–16 in cooperation with local growers on sandy clay and clay soils. The results are reported in tabular form. All combinations of fertilizers gave good returns for the money invested.

An application of 4 tons of lime per acre made in 1912 was followed by increased yields of cane of 4.98, 14.78, and 12.1 tons for 1913, 1914, and 1915, respectively.

A comparison of cultivation by hoes and by cultivator was made in 1915–16. Plats receiving four hoeings gave an acre yield of 27.02 tons, at a labor cost of \$10.41, while plats receiving five cultivations gave a yield of 25.03 tons, at a labor cost of \$8.41.

A demonstration of the value of crop rotation in practical cane culture, A. H. Rosenfeld (Sugar [Chicago], 18 (1916), No. 9, pp. 463, 464).—This is a popular discussion of crop rotation experiments with sugar cane conducted by the author while the director of the experimental work in Tucumán, Argentina. Continuous cropping with sugar cane is compared with cane following one year of cowpeas, corn, and alfalfa, respectively.

Remarkable increases in yield are reported. In a 3-year period, the highest gains were made after alfalfa, although the gains after corn were twice the average for the Province. The plats planted to cane after alfalfa showed an average annual gain of 3.5 tons per acre, the cane being superior in average stalk weight and slightly richer in juice than that following corn.

Some sugar cane experiments in Travancore, N. K. Pillai (Agr. Jour. India, 11 (1916), No. 1, pp. 79-81).—In experiments with sugar cane conducted during the 1914-15 season, the ridge and furrow system of planting seemed superior to planting in pits, the common practice in Travancore. Thin planting (5,000 sets per acre) was better than thick planting (10,000 sets or more). The application of a complete fertilizer was more profitable than that of ashes alone, as is the usual practice.

Washington wheats.—Their classification and identification, E. D. ALVORD (Wash. Agr., 9 (1916), No. 8, pp. 217-219, figs. 2).—A popular classification of 20 of the more common varieties of Washington wheats, based upon (1) head characteristics, and (2) kernel characteristics, each classification being complete in itself.

The wheat field in April.—Top-dressing with fertilizers may often be profitable, C. E. THORNE (Mo. Bul. Ohio Sta., 2 (1917), No. 4, pp. 110-112, fig. 1).—The wheat yields obtained at Wooster, Strongsville, Germantown, and Carpenter from fertilized and unfertilized plats in 3- and 5-year rotations and for good and bad seasons are tabulated.

An average increase in yield of 40 per cent at Wooster and 50 per cent at the substations was obtained in good seasons from applications of phosphorus and potassium. In bad seasons the increase was from 109 to nearly 200 per cent of the unfertilized yield. A further increase in the number of bushels was realized from applications of nitrogen, but the percentage of the unfertilized yields was smaller in good than in bad seasons.

With nitrate of soda selling at 3 cts. a pound or less, wheat at \$1 per bushel returned the cost of the nitrate in good seasons in all tests except at Strongsville. In bad seasons, however, wheat failed to return the cost of the nitrate at both Strongsville and Germantown. At the present price of nitrate (3.5 to 4 cts. per pound) wheat must bring more than \$1 a bushel to justify its use. The nitrate was in all cases preceded by a fall application of acid phosphate; otherwise the crop increase has never paid the cost of the nitrate.

For wheat fields not fertilized in the fall a top-dressing of approximately 200 lbs. of of acid phosphate and 50 lbs. of nitrate of soda in April is recommended. Sulphate of ammonia may be substituted for nitrate of soda, although its action is slower than that of the nitrate.

The saving of irrigation water in wheat growing, A. and Gabrielle L. C. Howard (Agr. Jour. India, 11 (1916), No. 1, pp. 14-30).—Wheat growing under irrigation in the Quetta Valley, India, is discussed with special reference to The fundamental principles of water the conservation of irrigation water. saving are formulated as follows: (1) Irrigation water should be spread over the largest possible area, as was demonstrated by Widtsoe (E. S. R., 32, p. 784). (2) Heavy waterings reduce the proportion of grain to total crop, causing an increase in the length and weight of straw. (3) The growing period of wheat is lengthened by heavy watering, thus delaying maturity, a very undesirable condition in the Quetta Valley, owing to the rapid rise in temperature and hot, dry, westerly winds. (4) When the water supply is limited the root development of the wheat crop will be deeper, provided the seed bed has been properly prepared. (5) Soil moisture must be preserved by the maintenance of a surface mulch of dry soil, accomplished by shallow harrowing.

Experiments on a somewhat extensive scale are reported in growing wheat with the natural moisture only and with a single irrigation. The yield without irrigation was approximately 28.8 bu. per acre. The single irrigation was applied in September, prior to sowing in October, and showed an increase of 5.8 bu. per acre over the yield obtained from fields receiving 7 irrigations. In addition to the increased yield, much earlier maturity was secured, together with a full development of the chaff color, rarely seen in the native-grown wheat.

Third annual report of the State grain laboratory of Montana, A. Atkinson, B. W. Whitlock, and E. W. Jahnke (Montana Sta. Bul. 113 (1916), pp. 77-100, figs. 21).—The work for the year ended September 30, 1916, is reported, including purity and germination tests of 5,035 samples, a study of the seed value of frosted wheat, and a study of the germinability of seeds at different periods after harvesting.

The weed seed content of samples of alfalfa, clover, timothy, and sweet clover is reported as having greatly increased.

The average field germination of frosted and unfrosted wheat was 75 and 78 per cent, respectively, while the average number of heads per row was 1,525

for the frosted wheat and 1,509 for the unfrosted wheat. The grain weight per row was 1,457 and 1,375 gm., respectively.

Germination tests of samples of winter and spring wheat, oats, and barley taken one week, one month, and two months after threshing indicate that germination improves greatly a few weeks after threshing.

Twenty-one of the worst weeds encountered in Montana are briefly described and illustrated.

Results of seed inspection, 1915 and 1916, J. P. Helyar et al. (New Jersey Stas. Bul. 302 (1916), pp. 3-23).—Continuing work previously noted (E. S. R., 34, p. 832), the author states that during the past two years more attention has been paid to the analysis of vegetable seeds offered for sale in bulk on the New Jersey markets. Analyses of official samples for 1915 include red clover, alfalfa, crimson clover, cowpeas, Canadian field peas, beans, lima beans, sweet corn, peas, radishes, tomatoes, turnips, cucumbers, and cabbages.

The 1916 analysis was confined entirely to vegetable seeds, except for crimson clover seed investigations. A comparison of the analyses of 29 crimson clover samples showed a variation in germination percentage of from 24.5 to 92.5 per cent.

Weeds in the Government of Novgorod, A. Malzew (*Trudy Bûro Prîkl. Bot. (Bul. Appl. Bot.)*, 9 (1916), No. 4, pp. 137-174).—The weeds found in winter rye, spring oats, barley, flax, potatoes, and cabbage in the Government of Novgorod are discussed, those peculiar to each crop listed separately, and all the weeds identified (81 in number) listed alphabetically and briefly described. It is pointed out that only about 12 of these weeds are serious pests and that as a rule the annuals are more noxious than the perennials.

Broom rape (Jour. Bd. Agr. [London], 23 (1916), No. 5, pp. 478-481, fig. 1).—This is a note on the parasitic weed broom rape (Orobanche minor), which was unusually prevalent in English clover fields during the summer of 1916. The life history of the plant is briefly outlined, together with preventive and control measures.

Red sorrel and its control (Rumex acetosella), F. J. PIPAL (Indiana Sta. Bul. 197 (1916), pp. 28, figs. 16).—Red sorrel is described and measures for its control outlined.

An abundance of red sorrel in a field is held to indicate soil acidity, insufficient organic matter or mineral plant food, or inadequate drainage. Pot tests with several types of soils indicated that correction of such unfavorable conditions will stimulate clover production and check the growth of the sorrel, although lime was not found to have harmful effects on the growth of the plant itself.

Other tests indicated that eradication of the weed may be effected by one or more applications in the form of a fine spray of a 20 per cent solution of sulphate of iron or of full strength orchard heating oil. For badly infested fields cultivation or grazing with sheep is recommended, and it is pointed out that pending eradication sorrel may be cut and utilized for feed.

### HORTICULTURE.

Proceedings of the American Society for Horticultural Science, 1916 (Proc. Amer. Soc. Hort. Sci., 13 (1916), pp. 162, pls. 3, figs. 6).—In addition to the routine business report, the following papers presented at the annual meeting of the society, held in New York City, December 28 and 29, 1916, are given: Methods of Work in Pruning Investigations, by C. H. Connors (pp. 14-17); Monographic Studies with Flowers, by A. C. Beal (pp. 17-22); Gardenia

Studies, by C. H. Connors (pp. 22-30); What Science Has Done and Will Do for Floriculture, by E. A. White (pp. 30-40); The Inheritance and Permanence of Clonal Varieties, by M. J. Dorsey (pp. 41-71); Experiments in Bud Selection with the Apple and Violet at Geneva, by R. D. Anthony and J. W. Wellington (pp. 71-76); Improvement of Vegetable Varieties by Selection, by R. Wellington (pp. 77-80); Variety Testing, by L. C. Corbett (pp. 80-84); Variety Testing at the Dominion Experimental Farms, and What Has Been Accomplished by It, by W. T. Macoun (pp. 85-90); Methods for the Study of Vegetable Varieties and Strains, by P. Work (pp. 91-95); Factors Influencing the Abscission of Flowers and Partially Developed Fruits of the Apple, by A. J. Heinicke (pp. 95-103); Horticulture as a Science and as an Art, by M. A. Blake (pp. 103-106); Influence of Nitrogen in Western Orchards, by C. I. Lewis (pp. 107-110); Report of the Committee on Research and Experimentation: Part I, by L. H. Bailey, Part II, Research and Experimentation, by W. L. Howard, Part III, How to Lay Out an Experiment in Horticulture, by H. J. Webber, and Part IV, Fundamental Training Required for the Successful Undertaking of Research, by W. T. Macoun (pp. 110-120); and Report of Committee on Graduate Courses, by M. J. Dorsey (pp. 120-128).

A list is given of horticultural projects being conducted at institutions with which members of the society are connected.

[Report of the] division of horticulture (Minnesota Sta. Rpt. 1916, pp. 49-54).—In the sterility studies with fruits the results with the strawberry indicate that where good pollen is produced in the cultivated varieties the plants are self-fertile. Studies conducted under tent and in the greenhouse show that a number of Burbank-Wolf plum crosses, as well as the Burbank plum, the sand cherry, and the Compass cherry, are self-sterile. Some of the hybrids of these fruits were intersterile. Self-sterility did not appear to be due to aborted pollen or defective nuclei. Studies were made of the flowers of five species of maples. The pollen of the partially suppressed anthers of the functionally pistillate flowers were found to be normal in all five species, but the flowers were self-sterile because dehiscence does not take place in this type of anther.

Of the hardy seedlings at the fruit breeding farm, Minnesota No. 4 raspberry is considered promising as it has sustained no winter injury in the last four seasons. At Deerwood it was not injured by a temperature of  $-49^{\circ}$  F. when left uncovered.

A test of ten varieties of Minnesota apples with reference to their value for cider and vinegar making showed that the apples are relatively low in sugar content but that vinegar of standard grade can be obtained within five months by pressing if kept in reasonably warm quarters.

A study of the most desirable time of the year for pruning apples and plums indicates thus far that success depends more on careful pruning than on the season in which the pruning is done.

Results of the potato investigations at the stations show conclusively that the improvement of seed by any kind of selection is an impossibility when the seed has been affected with curly dwarf. Tests made of potato seedlings and varieties showed in all cases that new stock is superior in productiveness and vigor to the old stock grown for one or more years in the station grounds.

Among the results secured in breeding various vegetables a pure line of Red Globe onion gives promise of being a valuable acquisition, owing to its good keeping quality. The work with squashes indicates the possibility of isolating and fixing a desirable commercial type of the Hubbard squash. In the tomato experiments marked increases in yield were obtained from some of the crosses, and it is believed certain combinations will prove valuable, owing to their earliness, smoothness, and productiveness.

Observations of various hedge plants on the station grounds indicate that the best plants for clipped hedges are buckthorn, *Cotoneaster acutifolia*, and Alpine currant. Hackberry and *Viburnum lantana* have been used with good results under some conditions.

[Report of horticultural investigations at the Crookston substation] (Minnesota Sta., Rpt. Crookston Substa., 1910–1916, pp. 70–81).—Tabular data are given showing the number and kinds of fruit trees and shrubs, as well as ornamental trees and shrubs planted at the Crookston substation chiefly during the period 1910–1916, including the number alive in 1916. Much injury and death among the plantings was caused by soil alkali, sun scald, freezing in the fall, and winter injury. The yields secured from variety tests of vegetables during the period of 1911–1916 are also reported, including notes on the best varieties.

[Horticultural work at the Crookston substation] (Minnesota Sta. Rpt. 1916, pp. 70, 71).—Notes are given on hardiness, variety, and cultural tests in 1915–16 of windbreak and ornamental trees and shrubs, orchard and small fruits, and vegetables, conducted at the Crookston substation, as noted above.

Report of the work of the horticultural substation, O. B. Whipple (Montana Sta. Bul. 114 (1916), pp. 101-123, figs. 8).—A progress report on orchard culture and variety tests started at the substation in 1908.

The results of cultural experiments taken as a whole show the detrimental effect of continuous clean tillage as maintained during the period 1908–1916, inclusive, and the beneficial effects of leguminous cover crops in building up the fertility of the soil. The variety tests included apples, apricots, cherries, pears, peaches, plums, and walnuts. Notes are given on the behavior and adaptability of different varieties to western Montana conditions.

A fruit survey of Mesa County, E. P. Sandsten, T. F. Limbocker, and R. A. McGinty (Colorado Sta. Bul. 223 (1917), pp. 3-52, figs. 12).—The survey here reported was conducted during the summer and fall of 1915. The area surveyed included the portion of Grand Valley, about 75,000 acres in extent, which was irrigated previous to the opening of the Government ditch in 1915. The information secured pertains to various cultural practices, the extent to which they are used, areas in different kinds of fruits, varieties grown, yields, costs, culture, etc. In presenting the results suggestions are given relative to improvement in cultural operations.

The results show that there are nearly 16,000 acres of orchard in the valley, of which 10,000 are apples, 3,000 peaches, 2,400 pears, and the remainder plums, apricots, and cherries. Fewer than one-third of the fruit trees in the Grand Valley are over 12 years old. The orchards as a rule were found to be too small to be profitable, the average size being slightly below 9 acres. The authors recommend that more land be devoted to general farming, stock raising, and dairying, and that the average fruit grower include other crops besides fruit. It is estimated that more than 2,500 acres of orchard have been pulled out during the last five years. The estimated average cost of production per box of fruit laid down at the shipping station is for apples 61.2 cts., pears 60.5 cts., and peaches 31.2 cts.

Fruits, trees, and shrubs recommended for northern Minnesota, T. M. McCall (Minnesota Sta., Rpt. Crookston Substa., 1910-1916, pp. 88-91).—The varieties given are listed in order of adaptability as shown by work at the Northwest Substation at Crookston and results obtained by growers in different parts of northern Minnesota.

Dependable fruits: Apples, pears, plums, peaches, cherries, small fruits, W. J. Green, P. Thayer, and J. B. Keil (Ohio Sta. Bul. 313 (1917), pp. 603-614, pl. 1).—This bulletin includes varietal lists prepared by the station of apples, pears, plums, peaches, cherries, and small fruits recommended for

culture in Ohio. The selection of the varieties here suggested for culture is based upon experience covering 25 years in the station orchard, in orchards of cooperators, and on observation and study of horticultural problems in various sections of the State.

Annual report of the Fruit Experiment Station, Shillong, for the year ended June 30, 1916, C. H. HOLDER (Ann. Rpt. Agr. Expt. Stas. Assam. 1916, pp. 64-85).—Tabular data are given showing the number and kinds of orchard and small fruits in the station nurseries and orchards.

Pruning, F. M. CLEMENT and F. S. REEVES (Ontario Dept. Agr. Bul. 248 (1917), pp. 36, figs. 78).—A practical treatise on methods of pruning fruit trees, vines, and bushes.

Apple breeding at the university experiment station, C. S. CRANDALL (*Trans. Ill. Hort. Soc.*, n. scr., 50 (1916), pp. 444-451).—A popular summary of progress made in apple breeding investigations which have been under way at the Illinois Experiment Station since 1907.

One phase of the work comprises an attempt to determine whether varieties of apples are affected through propagation from selected buds. The results secured indicate in brief that just as good trees are grown from small buds as from large buds, and there is no evidence that it makes any difference from which location on the tree or shoot the bud may be taken. Buds from water sprouts are equal to buds from top terminal shoots.

Field experiments in spraying apple orchards in 1916, A. J. Gunderson and W. S. Brock (Illinois Sta. Circ. 194 (1917), pp. 3-15).—The experiments here summarized were conducted to determine the relative values of Bordeaux and lime-sulphur in the control of apple blotch, the relative merits of dust and liquid spraying in the control of insects and fungi, and the value of the cluster-bud spray in the control of scab. A more detailed account will appear in a later publication.

Although Bordeaux caused some russeting of the fruit and a small amount of foliage injury, it proved superior to lime-sulphur as a spray for blotch, probably because of its greater adhesiveness. It was thus effective over a longer period of time than lime-sulphur. Dust mixtures were less efficient than the liquid sprays in the control of fungi, but apparently controlled the codling moth and curculio equally as well as the liquid sprays. The prebloom or cluster bud spray was valueless in the control of scab where the infection was not present the preceding season. Bordeaux applied just before the bloom was no more efficient than lime-sulphur arsenate of lead in the control of apple scab. On one plat where arsenate of lead was used alone throughout the season scab infection was reduced materially.

Based on results of the experiments, spray schedules are given for different sections of Illinois, together with formulas and methods of preparation.

Dominion experimental orchard work, W. S. Blair (Ann. Rpt. Fruit Growers' Assoc. Nova Scotia, 1917, pp. 132-159).—The results are given of cooperative spraying experiments conducted under the direction of the Kentville station in 1916.

The investigations as a whole show that four regular lime-sulphur arsenate sprays, the first of which is applied when the buds have burst and the leaves are partly open, the second when the blossom clusters have separated and before the petals have opened, the third when 90 per cent of the petals have fallen, and the fourth about ten days after the third spray, are necessary for the best control of apple scab. If three applications only can be made, a thorough application should be given midway between the time for the first and second sprays. If only two applications can be made, the one before and the one after the blossoms will give the best results.

In view of the less serious injury from burning, lime-sulphur lead arsenate was more satisfactory than other sulphur lead arsenate sprays and Bordeaux lead arsenate sprays. The kind of nozzle was not a factor in causing foliage injury, provided an equal amount of spray was applied. A heavy application of lime-sulphur lead arsenate is liable to cause foliage injury, whereas the regular application will cause very slight, if any, injury.

In order to avoid the injury from the drench spray of the combined nicotin sulphate and lime-sulphur lead arsenate used for the green apple worm, it seems necessary to reduce considerably the strength of the lime-sulphur solution. Lime-sulphur weaker than the standard 1.008 or 1:37 is not so effective for scab control.

The culture of small fruits on irrigated sandy land, R. W. Allen (Oregon Sta. Bul. 142 (1917), pp. 3-14, figs. 2).—The results of varietal and cultural experiments with strawberries, together with variety tests of currants, gooseberries, dewberries, raspberries, and blackberries, conducted at the Umatilla substation are here briefly stated, and cultural directions are given for growing small fruits based on the substation's work.

Fruiting habits of budded trees of the different avocado varieties, T. U. BARBER (*Rpt. Cal. Avocada Assoc.*, 1916, pp. 98-103 fig. 1).—A list is given of varieties of budded avocada trees which are fruiting in California and the age that they started to bear, together with a discussion of different characteristics of growth. The data given are based upon reports from members of the California Avocada Association.

Cultural experiments with the filbert in the East, J. S. McGlennon (Amer. Nut Jour., 6 (1917), No. 5, p. 71).—A brief statement of results secured in propagating and growing filberts during the past three seasons, including a list of varieties grown.

Analyses of materials sold as insecticides and fungicides for 1916, C. S. CATHCART and R. L. WILLIS (New Jersey Stas. Bul. 301 (1916), pp. 5-16).—The results are given of analyses of various samples of Paris green, lead arsenate, lime-sulphur, Bordeau mixture, and miscellaneous materials inspected by the station during the year 1916.

#### FORESTRY.

The training of a forester, G. PINCHOT (Philadelphia and London: J. B. Lippincott Co., 1917, 3. ed., rev., pp. 157, pls. 8).—In the present edition of this work (E. S. R., 30, p. 742) the facts and figures have been revised throughout and brought up to date, and a new chapter containing some essential information about American forests has been added.

The theory and practice of working plans, A. B. RECKNAGEL (New York: John Wiley & Sons, 1917, 2. ed., rev., pp. XIV+265, pls. 6, figs. 8).—The present edition of this work (E. S. R., 28, p. 644) has been thoroughly revised to embody the recent developments in forest organization.

Determining the quality of standing timber, S. Berry (Jour. Forestry, 15 (1917), No. 4, pp. 438-441).—An account of methods of determining the value of stands involved in stumpage appraisals as used in District 5 of the Forest Service of the U. S. Department of Agriculture.

Forest tree planting camps, J. S. ILLICK (Jour. Forestry, 15 (1917), No. 4, pp. 394-409).—In this article the author describes the methods employed by the Pennsylvania forest department in the establishment and operation of tree planting camps.

Eleventh report of the forest commissioner of the State of Maine, 1916, F. E. Mace (*Rpt. Forest Comr. Maine, 11 (1916), pp. 157, pls. 13, fig. 1*).—This report embraces various forest activities in Maine during 1915 and 1916,

including work of forest protection, forest extension and improvements, and forest education. A statement by G. B. Posey of the U. S. Department of Agriculture relative to the extent and distribution of the white-pine blister rust in Maine is also included.

The conservation law as amended to the close of the regular session of 1916 (Albany, N. Y.: State, 1916, pp. 409).—This comprises the conservation law of the State of New York dealing with the administration of lands, forests, and parks, fish and game, waters, and the State reservation at Saratoga Springs.

Report of the forestry branch (Rpt. Min. Lands, Forests and Mines, Ontario, 1916, pp. 146-151, pl. 1).—A brief report on forestry nursery work, white pine blister rust inspection, and railway fire protection in Ontario for the year ended October 31, 1916.

Fifty years of forest administration in Bashahr, H. M. GLOVER (Indian Forester, 41 (1915), No. 11, pp. 398-407, pls. 4; 42 (1916), No. 3, pp. 119-129, pls. 2).—In the present article the author considers the general effects of regular management during the last 50 years on the forests of Bashahr State, India, and the way in which the development of the forests has reacted on the prosperity of the State.

Notes on the forests of Algeria, Marc (Notes sur les Forêts de l'Algérie. Algiers: Gouvt. Gén. Algérie, Div. Forêts, 1916, pp. 333, pls. 15).—This work comprises as a whole a report on the past and present status of forestry in Algeria. The subject matter is presented under the following general headings: Forest revenues, the cork harvest, the forests and the transportation tariffs, forest activities from 1902 to 1914, forest fires in Algeria, measures taken in favor of the natives, lands withdrawn from the forest reserve from 1892 to 1915, and the accessory functions of the forest service in Algeria.

A discussion of Australian forestry, with special reference to forestry in western Australia, the necessity of an Australian forest policy, and notices of organized forestry in other parts of the world, together with appendixes relating to forestry in New Zealand, forestry in South Africa, and control of the rabbit pest, D. E. Hutchins (Perth, Aust.: Govt., 1916, pp. XXIII+434, pls. 17).—The present discussion embraces the results of a survey of forestry and forest conditions in Australia conducted under the auspices of the government of western Australia. Although special consideration is given to the forests of western Australia, the subject matter deals also with forestry in all the States of the Commonwealth and New Zealand.

Correlation between the light and soil requirements of a species for its natural regeneration, B. O. COVENTEN (Indian Forester, 43 (1917), No. 4, pp. 186-194).—A discussion of this subject with special reference to Indian species of trees. The principal species are here classified with reference to both light and soil requirements.

The biology of lodgepole pine as revealed by the behavior of its seed, C. G. Bates (Jour. Forestry, 15 (1917), No. 4, pp. 410-416).—The author briefly reviews the nature and results of seed production, extraction, and germination tests with lodgepole pine conducted by the Forest Service of the U. S. Department of Agriculture, and presents some deductions based on these experiments relative to the biology of lodgepole pine.

The Mexican and Central American species of Ficus, P. C. STANDLEY (U. S. Nat. Mus., Contrib. Nat. Herbarium, 20 (1917), pt. 1, pp. VIII+35).—This comprises a systematic description of the Mexican and Central American species of Ficus. Forty-one species are here enumerated, of which only two are common to the West Indies and Central America.

Forest and shade trees and basket willows recommended for planting in Idaho, C. H. Shattuck (Idaho Sta. Circ. 4 (1917), pp. 4).—A descriptive list

of trees recommended for various planting purposes in Idaho, including a price list of trees which the department of forestry of the station is prepared to furnish the residents of the State.

The status and value of farm woodlots in the eastern United States, E. H. FROTHINGHAM (U. S. Dept. Agr. Bul. 481 (1917), pp. 43, pl. 1, figs. 2).—The purpose of this bulletin is to show as nearly as can be done from available census statistics what the relation of the woodlot has been to the agricultural development of different parts of the East, what the tendencies appear to be, and, in general, what value the woodlot actually has to the Nation, the rural community, and the individual farm. The subject matter is presented under the general headings of woodlots of the Eastern States, how the growth of farming has affected the woodlot, amount and quality of woodlot timber, what the woodlot promises for the future, and the woodlot as a farm resource. In addition to considerable tabular data maps are given showing the proportion of woodland to total farm land in different sections of the East and the actual farm woodland area in the United States in 1910 by counties.

Canadian woods for structural timbers, H. N. Lee (Dept. Int. Canada, Forestry Branch Bul. 59 (1917), pp. 44, flgs. 22).—This bulletin gives a sketch of the forest resources of Canada and discusses the qualities that affect the usefulness of timber for structural purposes. Descriptions are then given of the chief Canadian species suitable for this purpose and comparisons, tables, and charts relating to mechanical and physical tests. The bulletin concludes with a short discussion of the grading of timber.

Forest products of Canada, 1913, 1914, and 1915, R. G. Lewis et al. (Dept. Int. Canada, Forestry Branch Buls. 52 (1915), pp. 79, pls. 2, figs. 5; 57 (1916), pp. 82, pls. 3, figs. 7; 58 (1917), pp. 72, pl. 1, figs. 8).—These comprise statistical reports for the years 1913, 1914, and 1915, respectively, relative to the use of lumber, lath and shingles, pulpwood, poles, and crossties throughout the Dominion. The production is given both by Provinces and by kinds of wood.

The recent industrial and economic development of Indian forest products, R. S. Pearson (Jour. Roy. Soc. Arts, 65 (1917), No. 3366, pp. 487-493).—A paper on this subject read before the Indian section of the Royal Society of Arts in April, 1917.

# DISEASES OF PLANTS.

The susceptibility of cultivated plants to diseases and pests, P. E. Keuchenius (*Teysmannia*, 27 (1916), No. 1-2, pp. 65-77).—This is a somewhat general discussion, with illustrative examples, of the several degrees of parasitism of economic plants, namely, infections induced by weakness, injury, or true parasitic activity of the attacking organism with the circumstances favorable thereto, as virulence, stage of development of host or parasite, physical conditions, and specializations.

Studies in the physiology of parasitism, W. Brown (Jour. Bd. Agr. [London], 23 (1916), No. 5, pp. 474-478).—This is a summary of work done and results obtained by the author and by Blackman and Welsford as previously noted (E. S. R., 37, p. 47).

A study of Glœosporium, Krüger (Mitt. K. Biol. Anst. Land u. Forstw., No. 15 (1914), pp. 15, 16).—A brief review is given of a few species (with their hosts) of Glœosporium, of which Colletotrichum is treated as a subgenus.

Further evidence as to the relation between crown gall and cancer, E. F. SMITH (*Proc. Nat. Acad. Sci.*, 2 (1916), No. 8, pp. 444-448).—Previous opinions are reviewed regarding cancer in animals and crown gall in plants. The author states that if inoculations with *Bacterium tumefaciens* are made in

regions not previously known to contain totipotent cells such as supposedly originate tumors on inoculation in the neighborhood of dormant buds, tumors are produced too numerously to be explained as due to the development of embryonic "cell rests" or what are conceived to be fragments displaced from the embryo in early stages of growth and remaining dormant amid other tissues. It is claimed that embryomas are the results of specific tissue responses to the stimulus of a specific schizomycete, taking the embryoma form if a complex anlage containing totipotent or nearly totipotent cells is involved. The conclusion is regarded as almost unavoidable that cancer is due to a parasite and that, as shown in case of plants, this parasite may be found to give rise to the most diverse forms of the abnormality.

Report of the pathologist, J. A. Stevenson (Rpt. Bd. Comrs. Agr. P. R., 5 (1915-16), pp. 35-74).—In addition to an account of routine work of the laboratory, the author gives descriptions of citrus and sugar cane diseases observed in Porto Rico. Notes are also given on a number of minor diseases, among them root knot of various ornamental and other plants, trunk rot of Ficus nitida due to Nummularia bulliardii, a root rot of avocado caused by an undetermined fungus probably of the Nummularia group, together with notes on entomogenous fungi.

[Reports on botany and plant diseases in Switzerland, 1913-14], H. MÜLLER-THURGAU ET AL. (Landw. Jahrb. Schweiz, 29 (1915), No. 5, pp. 476-484, 503-522, 574, 575, 578, 579, 593, 594).—The sections here noted relate to observations and experiments in connection with various phases of botany and plant parasitism, including disease resistance and injury by nematodes as well as by other animal pests.

Notes are given on a number of rather common parasites observed on various economic plants, the information being grouped according to whether the hosts are orchard, garden, or ornamental plants. There are also brief accounts of special studies on sugar in floral leaves; acetaldehyde formation in orchard fruits; hydrofluoric acid injury to grapes; cases of Phytophthora disease; control of Pseudopeziza tracheiphila on grapevines; Gnomonia on cherry leaves; control of Oidium euonymi japonica; a dieback of young plum trees probably due to root fungi; injury to ornamental plants by Aphelenchus ormerodis and Tylenchus dipsaci; and control of grape Peronospora, leaf roll of grape, and Sphærella fragariæ on strawberry.

Fungus parasites of the higher plants in the region of Kharkov and adjacent provinces, A. A. Potebnia (Kharkov. Oblast. Selsk. Khoz. Opytn. Sta., Fitopatol. Otd., No. 1 (1916), pp. 121-251, figs. 21).—In continuation of a previous report (E. S. R., 35, p. 453) an account is given of the ascomycetous parasites up to and including in part the Erysiphaceæ.

Of the Exoasceæ, species of Taphrina (in which the author includes the members of Exoascus) are found on a large number of hosts in four different families. Among Discomycetes, species of Sclerotinia and Pseudopeziza appear to be most prevalent. Particular attention is called to the occurrence of a little-known parasite, *Phacidiella discolor*, found on pear, apple, and *Pyrus paradisiaca*. This fungus causes serious trouble, however, only in case of apple, killing the bark on the trees and thus producing large wounds.

Diseases and pests of cultivated plants in the Dutch East Indies in 1915, C. J. J. VAN HALL (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Lab. Plantenziekten, No. 20 (1916), pp. 47).—An account is given of diseases and animal enemies affecting a large number of orchard, garden, forest, and field plants in Java during the year, with control measures employed or recommended, together with a list of phytopathological literature which appeared in 1915 relating to the Dutch East Indies.

Control measures against plant diseases and injurious insects, C. J. J. VAN HALL, A. A. L. RUTGERS, and K. W. DAMMERMAN (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Lab. Plantenziekten, No. 17 (1915), pp. 42, figs. 20).—This is a discussion of a large number of preparations, with devices and appliances for their employment, for the control of diseases and animal enemies of various plants in Java.

Tests of new fungicides, E. RIEHM (Mitt. K. Biol. Anst. Land u. Forstw., No. 15 (1914), pp. 7, 8).—The results are detailed of tests, principally with new mercury preparations offered as means of combating cereal diseases, particularly Tilletia tritici on wheat and Helminthosporium gramineum on barley.

Tests of fungicides with cereal diseases, E. Riehm (Mitt. K. Biol. Anst. Land u. Forstw., No. 16 (1916), pp. 8, 9).—The experiments noted above have been continued. The tests with mercury chlorophenol against Helminthosporium gramineum are said to have proved the adequacy of this fungicide in this connection. Chinosol proved less effective at safe concentrations. Mercury chlorophenol at 0.2 per cent concentration applied to seed grain for 10 minutes, or at 0.1 per cent for 15 minutes, controlled stinking smut as completely as did formaldehyde, copper sulphate, or corrosive sublimate, but it appeared to be ineffective against loose smut of barley.

Overwintering of stinking smut in soil, O. APPEL and E. RIEHM (Mitt. K. Biol. Anst. Land u. Forstw., No. 15 (1914), p. 6).—Spores of stinking smut in samples of soil from various localities could not be made to germinate in spring by any means employed.

Diseases and pests of rice, A. A. L. RUTGERS (Teysmannia, 27 (1916), No. 6, pp. 313-342).—Influences discussed as local causes of loss to rice interests include root rot (soil conditions), head rot (climate or weather), Tilletia horrida, Ustilaginoidea virens, Sclerotium rolfsii, fungus leaf spotting, and various insects and birds.

Treatment of loose smut of wheat and barley, O. Appel and E. Riehm (Mitt. K. Biol. Anst. Land u. Forstw., No. 15 (1914), pp. 5, 6).—After two hours in hot water and two more in moist air, wheat seed infected with loose smut showed a degree of infection amounting to 1 per cent. Complete freedom from infection was obtained by treating infected wheat or barley seed with 0.1 per cent corrosive sublimate for one hour, also by use of the combined treatment consisting of four hours in water at 25 to 30° C. and 10 minutes at 50 to 52°, likewise by use of the treatment in which barley seed are kept in water at 45° for two hours.

A wheat disease caused by Dilophospora graminis, L. Mangin (Bul. Soc. Path. Veg. France, 1 (1914) No. 1, pp. 55-77, pl. 1).—An account is given of the destructive effects on wheat of D. graminis. Dilophia graminis and Mastigosporium album, supposed to be other forms or stages of this fungus, are more or less common in wild grains, which may thus become sources of infection for wheat and perhaps oats, if not other crops.

[Wheat rust in New Zealand], R. Waters (Jour. Agr. [New Zeal.], 13 (1916), No. 1, pp. 41-46, fig. 1).—Wheat rust, though present to some extent every season in New Zealand, is rarely widespread and severe, but a period of exceptional severity in this respect was experienced in the neighborhood of Greenfield, Bruce County, South Otago, where yields were so greatly reduced as to be worthless in some cases. Volunteer oat plants in some badly rusted wheat fields showed practically no signs of rust.

Barberry is rare in many parts of New Zealand and it is not known to bear the fungus producing the æcidiospores of the wheat rust fungus, the usual mode of overwintering possibly being omitted in this case. It is believed that the summer spores infect the volunteer plants and autumn crops and that the spores produced thereon infect the spring crops. The Greenfield outbreak is thought to have originated from a crop planted in autumn.

The relation of weather to the development locally of the fungus is discussed, as are also subordinate related factors and some proposed methods of treatment, which include destruction of all aftermath and self-sown grain with avoidance of autumn and late spring sowing and of heavy nitrogen fertilizing.

Stalk disease of wheat, E. Foex (Bul. Soc. Path. Veg. France, 1 (1914), No. 1, pp. 26-30, pl. 1).—A brief discussion is given of foot disease of cereals, said to be due principally to Ophiobolus graminis, which works around the base of the stalk, and to Leptosphæria herpotrichoides, appearing higher on the stem, around which it also works its way more gradually. O. herpotrichus has been observed to cause stem weakening in cereals, as has also Cercosporella herpotrichoides, which has been considered a conidial form of Leptosphæria. Germination tests with these fungi are discussed.

Diseases of beans, W. G. SACKETT (Colorado Sta. Bul. 226 (1917), pp. 21-31, figs. 6).—Descriptions are given of a number of diseases of beans known to occur in Colorado, with suggestions for their control.

Among the more troublesome diseases are bacterial blight (Pseudomonas phaseoli), pod spot or anthracnose (Colletotrichum lindemuthianum), bean rust due to Uromyces appendiculatus, and a new disease to which the name bean streak has been given. The last disease was first observed in Colorado in the summer of 1916. It attacks stems, leaves, and pods, producing symptoms similar to those present in plants affected with bacterial blight. On the pods rusty, orange-brown discolorations later appear. The leaves are destroyed and the plants become defoliated before the crops mature. The cause and methods of control are being further investigated.

Control of clubroot of crucifers, O. APPEL and O. SCHLUMBERGER (Mitt. K. Biol. Anst. Land u. Forstw., No. 15 (1914), pp. 13-15).—Among the more favorable results tabulated as obtained from tests of preparations for reducing infection of cruciferous crops by Plasmodiophora brassicæ in the soil, those given by 2 or 3 per cent formalin and those by certain proprietary preparations were almost equal in value.

Phoma disease in crucifers, R. LAUBERT (Mitt. K. Biol. Anst. Land u. Forstw., No. 16 (1916), pp. 10-12, fig. 1).—It is considered probable that the same species of Phoma causes the more or less similar diseases of different cruciferous plants noted during recent years at points in Holland, France, Germany, Australia, and North America.

Corynespora melonis, Krüger (Mitt. K. Biol. Anst. Land u. Forstic., No. 15 (1914), pp. 16, 17).—C. melonis, the cause of leaf scorch of cucumbers, said to cause loss in England, Holland, and Germany, is briefly described and discussed as to effects and dispersal, with suggestions regarding seed disinfection.

Flax blight, G. Arnaud (Bul. Soc. Path. Veg. France, 1 (1914), No. 1, pp. 38-41, fig. 1).—Asterocystis radicis is said to cause a blight of cultivated flax in Flanders by attacking the roots and lowering water absorption. The intracellular behavior of the fungus is described. Alkalis seem to favor, acids to hinder, its development. Fungicides are difficult of application. Rotation of crops is recommended, though the parasite attacks also a number of common crops, which are named.

Studies in the dying out of pepper vines in the Dutch East Indies.—II, Pepper culture on Banka, A. A. L. Rutgers (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Lab. Plantenzickten, No. 19 (1916), pp. 36, pls. 17).—This contribution, in continuation of one previously noted (E. S. R., 35, p. 349), besides giving a brief history of pepper culture and its forms and characteristics on the island of Banka, deals briefly with such drawbacks as

unsuitable soil and animal and plant parasites, including nematodes (Heterodera radicicola) and an unnamed cobweb fungus on the leaves.

Potato diseases in the Dutch East Indies, Johanna Westerdijk (Teysmannia, 27 (1916), No. 1-2, pp. 1-15, pl. 1).—This is a discussion of potato varieties, culture, and diseases with related protective measures. The diseases include Phytophthora infestans, Macrosporium solani, leaf roll, a leaf rust, and a root fungus.

Experiments for control of potato canker, E. Werth (Mitt. K. Biol. Anst. Land u. Forstw., No. 16 (1916), pp. 9, 10).—Experiments with sulphur on the potato varieties Wohltmann, Silesia, and Industry gave a lowering of canker infection amounting to less than one-third, accompanied by a decrease of more than three-fourths in yield. Tests for resistance showed less than 10 per cent susceptibility in Kaiserkrone, Richter Imperator, Fürstenkrone, Gertrud, Schnellert, and Paulsen July.

Potato leaf roll in France, E. Foex (Bul. Soc. Path. Veg. France, 1 (1914), No. 1, pp. 42-48).—Potato leaf roll is said to attack severely several varieties of potato in the canton of Orchies in northern France.

Potato leaf roll, O. APPEL and O. SCHLUMBERGER (Mitt. K. Biol. Anst. Land u. Forstw., No. 15 (1914), pp. 8-11, fig. 1).—The authors continue to report on the study of potato leaf roll previously noted (E. S. R., 27, p. 247; 28, p. 52; 31, p. 52; 34, p. 443). The results obtained by planting the diseased stock from different sources on various soils were not consistent throughout. Improvement was noted in some cases, while in others the leaf roll appeared later in the season.

Chlorosis of beets, G. Arnaud (Bul. Soc. Path. Veg. France, 2 (1915), No. 2, pp. 123, 124).—Describing the foliar discoloration in sugar beets previously noted by Berthault (E. S. R., 35, p. 350) and by Miège (E. S. R., 36, p. 543), the author states that the trouble was somewhat general in the north of France during 1915. It is thought that the phenomenon is related causally to the prevalence of Cercospora beticola, Uromyces betw. Phoma tabifica, and leaf aphids, in connection with lack of water, cultivation, and fertilizers, and with late seeding.

Crown gall of sugar beets, Peters (Mitt. K. Biol. Anst. Land u. Forstw., No. 16 (1916), pp. 12, 13, fig. 1).—In 1912, beets penetrated to a depth of 2 to 3 cm. with a needle which had been dipped in cultures of Bacillus tumefaciens showed partial, or doubtful, results. On repeating the tests the next year, however, and using also shallower penetration (0.5 to 1 cm.), a high percentage of the plants so treated developed crown gall, while the controls were free from enlargements.

Sweet potato diseases, J. A. McClintock (Virginia Truck Sta. Bul. 22 (1917), pp. 455-486, figs. 14).—Popular accounts are given of diseases of the sweet potato, with suggestions for their control.

The diseases are classified according to the part of the plant involved as those of the above-ground parts, those of the roots, and those of both vines and roots. For the control of many of the diseases, and especially of the more destructive of those affecting both vine and roots, the author recommends careful selection of seed tubers, their treatment with corrosive sublimate solution, and planting in seed beds in which clean sand has been substituted for soil. The cuttings should afterwards be planted in soil that is known to be not infected or where sweet potatoes have not been planted for several years.

Sclerotium disease of tobacco, Johanna Westerdijk (Meded. Deli-Proefstat. Medan, 10 (1916), No. 2, pp. 30-40, pls. 2).—A study of a disease of young tobacco, carried on at the Deli Station, is said to indicate that the trouble is

due to S. rolfsii, which flourishes on wild Crotalaria and probably on various other legumes which may be found growing with tobacco.

The parasitism of Coryneum on trees and shrubs, G. Abnaud (Bul. Soc. Path. Veg. France, 2 (1915), No. 1, pp. 64-70, figs. 3).—This is a bibliographical discussion of several species of Coryneum on different hosts named in relation with several other fungus forms.

Hail effects on trees, G. Arnaud (Bul. Soc. Path. Veg. France, 2 (1915), No. 2, pp. 121, 122, pl. 1).—Injuries, particularly to young trees, due to hail driven by strong wind in May, 1915, and observed in July and in October of that year, are described, and resemblances and differences are noted between such injury and the characteristic effects of fungi, in particular Nectria ditissima.

Behavior of apple canker in two grafts differing in susceptibility on the same stock, P. A. Dangeard (Bul. Soc. Path. Veg. France, 2 (1915), No. 2, pp. 127, 128).—A case is noted in which two varieties of apple, one very susceptible to Nectria and usually developing canker, and the other ordinarily very resistant thereto, were grafted on the same stock. The resulting growths both showed canker, the originally resistant one, however, in lesser degree. After the removal of the more susceptible half, the new growths on the other portion were free from Nectria.

A new Oospora on pear, L. Mangin (Bul. Soc. Path. Veg. France, 3 (1916), No. 1, pp. 9-11, figs. 2).—A brief account is given of a fungus attacking pear leaves and branches. It is considered a new species and described under the name O. piricola

Biological observations on pear rust, A. TROTTER (Riv. Patol. Veg., 8 (1916), No. 3, pp. 65-76).—A study of pear rust (Ræstelia cancellata), carried out near Avellino, has convinced the author that normally the fungus can not winter in that host but that its persistence from year to year in a given locality requires the presence of an alternate host. Juniperus sabina is noted as sustaining such relation in this locality, though several other junipers are known to harbor the fungus.

Disease of apricots in the Rhone Valley, J. CHIFFLOT and MASSONNAT (Bul. Soc. Path. Veg. France, 2 (1915), No. 2, pp. 117-120).—This has been previously noted (E. S. R., 35, p. 249).

Some observations on witches' brooms of cherries, H. Schmitz (Plant World, 19 (1916), No. 8, pp. 239-242).—The author, noting the results of observations and tests made in the course of a michrochemical study of witches' brooms of cultivated cherries due to Exoascus cerasi, holds these results to sustain the claims that witches' brooms elaborate much or all of the food materials needed for their own growth. The increased amount of stored food and resulting high osmotic pressure may account for the prolonged and rapid growth of the diseased parts. The fungus disturbs the normal periodicity of the affected region. Chlorophyll is only masked by the red color in the leaves on the broom. The red color is due to acidity in the leaves, which acidity may itself be due either to the hydrolytic influence of the fungus on the stored material or on the cell walls, or to an influence exerted by the fungus in prolonging the embryonic condition of the leaves and twigs, since even the leaves of the brooms lose their red color upon becoming fully mature.

The biology of Exoascus deformans and preventive treatment of peach leaf curl, V. Peglion (Staz. Sper. Agr. Ital., 49 (1916), No. 3-4, pp. 200-218; abs. in Riv. Patol. Veg., 8 (1916), No. 3, pp. 88, 89).—The important means of preservation and transmission of E. deformans, the peach leaf curl parasite, is said to be the ascospores, the effectiveness of these depending largely upon atmospheric conditions. The fungus is best controlled during the winter rest

of the trees by employing a spray made up of 2 per cent copper sulphate, 1 per cent lime, and 0.2 per cent ammonium chlorid.

A substitute for self-boiled lime-sulphur and other summer sprays for peaches, L. G. Gillam (New Jersey Stas. Circ. 63 (1917), pp. 2-4).—Directions are given for the preparation of a summer spray for peaches to be used as a substitute for self-boiled lime-sulphur. This fungicide is composed of 8 lbs. fine sulphur, 4 lbs. hydrated lime, and  $1\frac{1}{2}$  oz. ground glue dissolved in 3 gal. water, the whole diluted with water to make 50 gal. In the preparation of the spray the dry sulphur and lime should be mixed, then thoroughly incorporated with the glue solution before the addition of the water.

A test of this fungicide proved its value for preventing scab and brown rot without injury to the trees.

On a new canker disease of Prunus yedoensis, P. mume, and other species caused by Valsa japonica n. sp., T. Hemmi (Jour. Col. Agr. Tohoku Imp. Univ., 7 (1916), No. 4, pp. 257-319, pls. 4).—An account is given of a study on a disease first noticed in Sapporo in 1913 and at present limited to Hokkaido. It is common on P. yedoensis, P. sachalinensis, and P. mume, and is found also on P. persica and other species of Prunus. The trouble is said to be due to a new species of fungus of the subgenus Euvalsa, which has been named V. japonica. It may simply cause a canker or else a girdling disease of a different type on the branches.

In the saprophytic condition *V. japonica* seems almost omnivorous. As a parasite it attacks its host most readily through old wounds having a layer of dead cells. Gummosis always develops as a result of the invasion.

Treatment with copper sulphate and sodium carbonate appears to be ineffective. Corrosive sublimate at from 0.05 to 0.1 per cent is the most effective fungicide employed in this connection.

Dieback in currant, O. Appel and E. Werth (Mitt. K. Biol. Anst. Land u. Forstw., No. 16 (1916), pp. 13, 14).—A dieback of currant bushes, extending from a center and increasing the second year (resistance differing with varieties), is ascribed to Plowrightia ribesia. Somewhat different from this fungus as to mode of development, but resembling each other in some ways, are dieback diseases ascribed respectively to Botrytis cinerea and to Pleonectria berolinensis, to both of which all varieties appear to be about equally susceptible.

Peronospora in 1915, and its control, A. Marescalchi (Ann. R. Accad. Agr. Torino, 58 (1915), pp. 349-357, figs. 7; abs. in Riv. Patol. Veg., 8 (1916), No. 3, pp. 81, 82).—The very violent outbreaks of downy mildew occurring May 24 and 25, June 4 and 5, and June 27 and 28, with one of lesser violence May 10 to 12, are said to be closely connected with the high temperature, humidity, and cloudiness which were common in 1915, but not so closely with the actual amount of precipitation. The author points out the necessity for the early and effective dissemination of information regarding the imminence of mildew attack and the necessity for timely sprayng.

Treatment of Peronospora during 1915, E. C. D'Albaretto (Ann. R. Accad. Agr. Torino, 58 (1915), pp. 304-312).—Giving an account, with discussion, of experiences in connection with the unusually violent grape downy mildew outbreaks of 1915, the author states that while in some cases from 10 to 20 sprayings were ineffective as regards control, five sprayings with the ordinary copper solutions controlled the mildew with a great saving of materials and labor. The precise observance of the prescribed manner and times of spraying is thought to be essential to success in dealing with grape downy mildew and to be sufficient even in years of unusually unfavorable conditions.

The germination of the winter spores of Plasmopara viticola, L. RAVAZ and G. VERGE (Bul. Soc. Path. Veg. France, 1 (1914), No. 1, pp. 51-54).—This is a summary of the development and existing state of knowledge regarding the autumn, winter, and spring behavior of P. viticola on Vitis vinifera.

The present status of the coconut bud rot disease, J. R. Johnston (Habana: 1916, June, pp. 8, fig. 1).—The author states that coconut bud rot is an internal disease of the terminal bud. This fact precludes the employment of pruning except in the initial state (which it is practically impossible to determine), and also the external use of germicides. The slow growth of the tree, moreover, practically prevents the employment of breeding for resistant varieties.

In Cuba, for which somewhat complete records have been obtained and summarized herein, the disease was destructive as early as 1886. It is also said to have been reported as causing, or as having caused, loss in British Guiana, Jamaica, Trinidad, the Cayman Islands, and the lesser Antilles, but its presence is denied or doubted in some other localities which are mentioned.

Fungi parasitic on the tea plant in northeast India, V, VI, A. C. TUNSTALL (Indian Tea Assoc., Sci. Dept. Quart. Jour., 1915, Nos. 1, pp. 12-16; 3, pp. 53-56).—Continuing the series of reports previously noted (E. S. R., 33, p. 650), the author states that Exobasidium vexans, the cause of blister blight, attacks leaves and stems and, in general, only young succulent growths of tea plants and no jungle plants so far as known. The spores die after two or three days and the fungus a little later. It is thought, therefore, that the fungus has no dormant stage. On many tea gardens in Assam the disease dies out spontaneously. In the hilly districts, bushes in damp, shady places may show the blisters at any time of the year. Under favoring conditions, the disease may spread with great rapidity.

Fomes lucidus is a common cause of root disease in tea bushes. Pestalozzia palmarum causes a gray blight of alder leaves and is sometimes found on the stems. The fungus is common in the jungle on both dead leaves and living plants, but it does little harm so long as the plants are healthy. A dieback of weakened plants is due to at least one species of Glæosporium. A closely similar disease ascribed to Colletotrichum camelliæ is prevented by sprays and soil improvement. Internal root disease is ascribed to various species of Diplodia, the commonest being Botryodiplodia theobromæ, a fuller report of which is to be given later.

Tumors on Chrysanthemum frutescens, R. Laubert (Mitt. K. Biol. Anst. Land u. Forstw., No. 15 (1914), p. 17).—The author notes the occurrence on C. frutescens chrysaster, near Berlin, of enlargements or outgrowths similar to those designated in America as crown gall, and supposedly due to infection with Bacterium tumefaciens.

Canker of cleander, P. Harior (Bul. Soc. Path. Veg. France, 2 (1915), No. 1, pp. 38-40, fig. 1).—Briefly describing a disease of cleander, which is said to attack any organ thereof, causing enlargements which are described, the author mentions approvingly the views of Tonelli, who supposed the trouble to be of bacterial causation and to be favored as to transmission by the activity of insects (E. S. R., 29, p. 156).

A new fungus parasitic on Ceara rubber trees, F. Vincens (Bul. Soc. Path. Veg. France, 3 (1916), No. 1, pp. 22-25, figs. 6).—A brief account is given of a disease of Manihot glaziovii observed in 1913 north of the bay of Rio Janerio. The causal fungus, which is considered to be a new species, is described as Haplographium manihoticola.

Diseases of Hevea brasiliensis in the Amazon Valley.—I, Leaf diseases, II, Trunk diseases, F. Vincens (Bul. Soc. Path. Veg. France, 2 (1915), No. 1, pp. 11-27, 54-63, pls. 3, figs. 7).—Fungi noted in connection with diseases or

abnormalities of *H. brasiliensis* include forms more or less reliably identified with *Dothidella ulei*, *Fusicladium macrosporum*, *Phyllachora huberi*, *Aposphæria ulei*, *Colletotrichum* (*Glæosporium*) heveæ, *Pestalozzia palmarum*, and *Phyllosticta* sp., besides the supposedly new species *Scolecotrichum heveæ*, *Fusarium heveæ*, *Zygosporium paraense*, *Cercospora heveæ*, and *Meliola heveæ*, some of the above being compared with other forms.

Trunk and branch diseases mentioned in the second article as of considerable importance include those caused by Fusicladium macrosporum and G. alborubrum. Organisms of less importance are Cephaleuros virescens, Botryodiplodia theobromæ, a Corticium, and a Microthyrium.

Diseases of Hevea in Ceylon, T. Petch (*Trans. 3. Internat. Cong. Trop. Agr. 1914, vol. 1, pp. 596-607*).—A preliminary abstract summarizing the principal points in this paper has been noted previously (E. S. R., 34, p. 849).

The effects of asphyxiating gases on forest vegetation, F. Döß (Rev. Eaux et Forêts, 54 (1916), No. 7, pp. 192-195; abs. in Forestry Quart., 14 (1916), No. 4, p. 748).—Giving a brief account of the results of gas attacks in the Champagne in October, 1915, the author states that while grapevines, cruciferous garden crops, and deciduous forest trees were not seriously injured, ornamental plants were severely damaged. Conifers showed the injurious effects in a yellowing and shedding of leaves, recovery from which had become apparent, in some cases at least, by May 15, 1916.

A beech disease due to Nectria ditissima, M. Guinier (Bul. Soc. Path. Veg. France, 2 (1915), No. 2, pp. 91-92).—The author records, supposedly for the first time, a mode of attack by N. ditissima, in which the fungus starts on a young branch and kills the tissues for a certain distance, thus causing the death of the portion beyond.

Galls on juniper, P. Hariot (Bul. Soc. Path. Veg. France, 2 (1915), No. 1, pp. 8-10, fig. 1).—A description is given of a juniper gall associated with a fungus which is thought to be Ceratostoma juniperinum, hitherto unknown in France.

Peridermium strobi on Swiss pine, E. Werth (Mitt. K. Biol. Anst. Land u. Forstw., No. 16 (1916), pp. 14, 15).—A disease causing blister rust on Swiss pine was tested as to its ability to attack Ribes. Experiments proved successful in those cases in which the infected Ribes plant was kept under a bell glass. The fungus is therefore considered to be identical with P. strobi.

Dry rot, P. Groom (Jour. Bd. Agr. [London], 23 (1916), No. 5, pp. 465-474, figs. 12).—A brief discussion is given of Merulius lacrymans, Coniophora cerebella, and Polyporus vaporarius, including conditions favorable to infection and development and measures for control of the dry rot fungi, which are said to cause immense losses annually in the United Kingdom.

## ENTOMOLOGY.

The nature of the polyhedral bodies found in insects, R. W. GLASEB and J. W. CHAPMAN (Biol. Bul. Marine Biol. Lab., Woods Hole, 30 (1916), No. 5, pp. 367-390, pls. 3).—The authors' investigations of the nature of polyhedral bodies carried on in connection with the work previously noted (E. S. R., 33, p. 856) have been summarized as follows:

"Polyhedral bodies are found in many different species of lepidopterous larvæ. The bodies are specific for a certain type of disease. The polyhedra vary in size in the different species. There exists a striking similarity in shape between the polyhedra found in different species. The polyhedra are structurally complicated. They arise in the nuclei of certain tissue cells. Cytoplasmic inclusions are found in certain diseases of higher animals. Nuclear in-

clusions have not been known previously. The polyhedra are nucleoprotein crystal-like degeneration products and not organisms. The polyhedra contain iron and phosphorus. On dissolving polyhedra in alkali and after dialyzing away the alkali and evaporating the protein solution crystals are obtained which simulate the original polyhedra."

A bibliography of 23 titles is included.

Some facts relative to the influence of atmospheric humidity on insect metabolism, T. J. Headlee (Jour. Econ. Ent., 10 (1917), No. 1, pp. 31-38).— The author's studies indicate that the speed of metabolism in the pupæ of both the bean weevil and the Angoumois grain moth varies inversely with the atmospheric humidity. In the adult of the former it varies with, while in the adult of the latter it varies inversely with, the humidity. In the egg stage the speed of metabolism varies inversely with the humidity, but in the larvæ and in the life cycle as a whole it varies with the humidity. It was found that reproduction of the bean weevil in tightly closed jars can be prevented by the introduction of sufficient concentrated sulphuric acid to keep the atmospheric humidity low.

Methods used in determining wind dispersion of the gipsy moth and some other insects, C. W. Collins (Jour. Econ. Ent., 10 (1917), No. 1, pp. 170-177, pls. 2).—"Additional data [E. S. R., 33, p. 653] have been collected on long-distance wind dispersion of gipsy moth larvæ; namely, across Cape Cod Bay off the coast of Massachusetts. The direction of the wind, recorded at the time taken and previously, indicated the source of infestation to be from 19 to 30 miles distant on the mainland. Frequent examinations of the screens and close data kept on movements and direction of the winds were necessary to make these records of value.

"Screens used in the cranberry bog experiments and placed horizontally over the vines were well adapted to catch the drop of small larvæ floating over such areas, while the upright wire and cloth screens proved better for securing long distance spread.

"The recording of three extra lepidopterous species and possibly a fourth being carried by the wind in the larval stage suggests some possibilities for investigation with others along this line."

A method for the study of underground insects, J. W. McColloch (Jour. Econ. Ent., 10 (1917), No. 1, pp. 183-188, fig. 1).—The author has found that the use of a 6-foot excavation in the ground, the sides of which are boarded up or cemented and a roof added, permits the rearing of subterranean insects at a fairly constant temperature. The fact that the daily range of temperature is small makes it possible to hold it at any desired degree for some time. The conditions in the cave have appeared to approximate those that would be encountered in the field by the subterranean forms studied.

Sixteenth report of the State entomologist of Connecticut for the year 1916, W. E. Britton (Connecticut State Sta. Rpt. 1916, pt. 2, pp. VII+65-146, pls. 16, flgs. 3).—Following a report of nursery and apiary inspection, work with the gipsy and brown-tail moths is discussed. An account is next given of the turnip aphis (Aphis pseudobrassica) which was widely destructive during the year in Connecticut. Brief reference is made to the control of aphids in fields of seed beets in which it is stated that blackleaf 40 proved a satisfactory remedy. General accounts are given of the white-marked tussock moth and the rose chafer.

Experiments in controlling the striped cucumber beetle and the squash borer are briefly described by W. E. Britton and Q. S. Lowry (pp. 116-118). The striped beetle was more abundant than has ever been observed elsewhere and

ruined nearly all plants notwithstanding various treatments that were applied. The greatest benefit obtained in control measures with the squash borer was followed by the combined treatments of cutting out the borers and covering the vines with soil.

An outbreak of the eight-spotted forester (Alypia octomaculata) at New Haven in which grapes and the Virginia creeper were defoliated is reported upon by Q. S. Lowry (pp. 118–122), as previously noted (E. S. R., 37, p. 158). Arsenate of lead at the rate of 3 lbs. to 50 gal, of water was found to be very effective, one spraying being sufficient in most cases. The pine tip moth (Pinipestis zimmermani) was reared from material collected in several counties and apparently occurs throughout the State. The parallel spittle insect on pine (Aphrophora parallela), reported upon by B. H. Walden (pp. 125, 126), is said to have been quite abundant in the forest plantations at Rainbow during the past two or three seasons. Antimosquito work in Connecticut during 1916 is reported upon by W. E. Britton and B. H. Walden (pp. 126–138). The entomological features of 1916 are briefly referred to.

The work concludes with accounts of miscellaneous insects of which mention may be made of a scale on azalea (Eriococcus azalea), the European elm case bearer (Coleophora limosipennella), another spruce gall aphid in Connecticut (Chermes coolegi) infesting the Colorado blue spruce at Hartford, injury by silverfish (Thermobia domestica), a scolytid beetle (Xyleborus dispar) which tunnels in the trunk of sugar maple, the walnut caterpillar (Datana integerrima) which was prevalent during the year, the tarnished plant bug injuring tobacco, the greenhouse leaf tyer (Phlyctania ferrugalis) which damaged snapdragons, geranium, and cineraria at Norwalk in January, a fleabeetle (Œdionychis sexamaculata) found at Middlebury feeding on ash, white grubs injuring California privet, the grapevine sawfly (Erythraspides pygmaus), Euclemensia bassettella, a microlepidopteran reared from a coccid thought to be Kermes sassceri, termites injuring shotgun cartridges, the girdling of hardwood twigs by Vespa crabro, the hickory gall aphid (Phylloxera caryacaulis), and the grapevine tomato gall (Lasioptera vitis).

Fourteenth annual report of the State entomologist of Montana, R. A. Cooley (Montana Sta. Bul. 112 (1916), pp. 53-76, fig. 1).—The first part of this report consists of brief notes on the occurrence of the more important insect pests of 1916. This is followed by a review of the principal State interests in entomology in 1916, including the occurrence of and quarantine work against the alfalfa weevil, army cutworm, wheat sheath miner (Cerodonta femoralis), sugar-beet root louse (Pemphigus betæ), lesser clover leaf weevil (Phytonomus nigrirostris), spinose ear tick (Ornithodoros megnini), and foul brood of bees. Notes on the More Common Mosquitoes of Montana, by J. R. Parker (pp. 69-75) follow.

Notes on several insects not heretofore recorded from New Jersey, H. B. Weiss (Jour. Econ. Ent., 10 (1917), No. 1, p. 224).—The sawflies Janus abbreviatus and Diprion simile are recorded as occurring at several points in New Jersey. The columbine leaf miner (Phytomyza aquilegiæ) is a local pest of columbine at several points in the State, and a large roach (Blaberus discoidalis) has been found several times in greenhouses, having been introduced on orchids imported from South America.

Report of the entomologist, G. N. Wolcott (Rpt. Bd. Comrs. Agr. P. R., 5 (1915-16), pp. 75-85, pl. 1).—This is a brief summary of the activities of the year, including inspection and quarantine work, citrus insect, tobacco insect, and sugar-cane insect investigations. Analyses of sugar cane free from and infested by Diatraea saccharalis are included.

Report on tobacco and vegetable insects, R. T. COTTON (Rpt. Bd. Comrs. Agr. P. R., 5 (1915-16), pp. 86-99, figs. 3).—Particular attention was given to flea-beetles, of which four species, namely, Epitrix cucumeris, Systema basalis, E. parvula, and E. fuscata, attack tobacco, ranking in importance in the order named. The eggs of these beetles are deposited about the roots of the plants, upon which the larvæ feed, and the leaves are attacked by the adults.

E. cucumeris, unlike the other species of the genus, is present throughout the year and does a great deal of damage. Its eggs hatch in 5 days, the larvæ feed from 20 to 35 days, and 6 days are passed as a pupa. E. purvula, which is the third in importance, usually causes injury during dry spells. Its eggs hatch in 5 days and the larvæ feed for from 15 to 25 days, the pupal stage lasting for a period of 6 days. E. fuscata, which is occasionally found doing damage to tobacco, is very similar in its habits to E. cucumeris.

S. basalis, the largest of the flea-beetles that attack tobacco, is present in great numbers throughout the year. Its eggs hatch in 12 days, from 20 to 35 days are passed in the larval stage, and 9 days in the pupal stage. Preventive measures include the destruction of weeds and bushes that grow near tobacco fields. The seed beds and the young plants in the field should be kept dusted with a mixture consisting of 3 per cent Paris green and 97 per cent corn flour or leached wood ashes. Diplumbic arsenate of lead when used as a spray at the rate of 3 to 4 lbs. per 100 gal. of water also gives good results. When used as a dust it should be applied with at least an equal amount of dry wood ashes.

In reporting upon vegetable insects the author estimates that there is a 20 per cent annual loss due to their ravages. Two of the more abundant and destructive pests were studied, namely the chrysomelid beetles Cerotoma ruficornis and Diabrotica graminea. C. ruficornis feeds upon beans and cowpeas and when abundant strips the leaves to their veins and midribs. The damage is not confined to the beetles alone, for the larvæ which live in the soil around the roots of the beans, feed on the roots and nodules and make furrows in the subterranean portion of the stem. The eggs, which are laid in the soil upon the roots of the host plant, hatch in 8 days, the larvæ feed for a period of from 25 to 30 days before pupating, and from 5 to 8 days are passed in the pupal stage. The methods of control consist in the collection of the beetles as they first appear and spraying with a mixture of Bordeaux and arsenate of lead at the rate of 3 lbs. of the latter to 50 gal. of spray.

D. graminea is a source of injury to all kinds of truck crops, breeding as it does continuously throughout the year. The principal damage is done by the adult beetles, which feed on the foliage and flowers of the tender young plants; the larvæ feed on the roots of a number of plants, which they may seriously weaken. The eggs are deposited in the soil about the base of the plant and hatch in 8 days. The larvæ, which feed for a period averaging 22 days, generally attack the roots from the outside, but occasionally bore into the tissues of the plant at the crown. From 6 to 9 days are passed in the pupal state. The entire life cycle from egg to adult requires at least 36 days.

The sweet potato root borer (*Cylas formicarius*) has become a bad pest in Porto Rico only in the district near Fajardo known as "Las Cabezas," although present in small numbers in many parts of the island. The sweet potato scarabee (*Cryptorhynchus batatæ*) has also done considerable damage to sweet potatoes in Porto Rico.

"Experiments with plant lice and lace bugs on peppers, eggplant, and cucumbers showed that blackleaf 40 applied at the rate of 1 fluid ounce to 8 gal, of water plus 0.5 lb. of whale-oil soap gave perfect control. Arsenate of lead applied at the rate of 2.5 lbs. to 50 gal, of water gave excellent results in the control of the leaf-feeding larvæ of the moth Xylomeges sunia and the leaf-

eating beetles *C. ruficornis* and *D. graminea*. Further experiments with the 'changa' showed that almost perfect control may be obtained by surrounding the young plants when they are planted out in the field with a ring of the Paris green and flour mixture. This mixture consists of 3 per cent Paris green and 97 per cent of a flour high in gluten."

Important foreign insect pests collected on imported nursery stock in 1916, E. R. Sasscer (Jour. Econ. Ent., 10 (1917), No. 1, pp. 219-223).—A summary of the more important results of Federal inspection work.

Some methods of colonizing imported parasites and determining their increase and spread, S. S. Crossman (Jour. Econ. Ent., 10 (1917), No. 1, pp. 177-183, fig. 1).—The author describes the methods made use of at the Gipsy Moth Laboratory of the Bureau of Entomology of the U. S. Department of Agriculture.

Efficiency and economy in grasshopper control, E. D. Ball (Jour. Econ. Ent., 10 (1917), No. 1, pp. 135-139, fig. 1).—The author describes a grasshopper catching machine which is efficient, inexpensive, and when once built is always ready for immediate use. The details of its construction have been given in a bulletin previously noted (E. S. R., 33, p. 59). The machine takes 24 ft. at a sweep, and 40 acres can be covered in a day.

The seventeen-year locust in western New York, C. H. Hadley, Jr. and R. Matheson (Jour. Econ. Ent., 10 (1917), No. 1, pp. 38-41).—The authors record the occurrence of this insect during the summer of 1916.

Biological and systematic notes on British Thysanoptera, C. B. WILLIAMS (Entomologist, 49 (1916), Nos. 641, pp. 221–227, fig. 1; 642, pp. 243–245; 643, pp. 275–284).—The author's studies have led to the conclusion that the American pear thrips (Taniothrips pyri) is no other than T. inconsequens, a species which has been known to occur in England for nearly 100 years, and which does not usually cause much injury in Europe. The author considers it practically certain that the species was introduced into California from Europe in the larval or pupal stage in the soil attached to the roots of fruit trees. Its spread from there to other parts of the United States, and recently into Canada, may have been by the same means, or by the rapid transference of adults by railway trains, etc., or it is possible that a fresh introduction from Europe might have occurred. Its distribution as now known includes Bohemia, Italy, England, the United States, and Canada.

In further notes on the pea thrips Kakothrips pisivora (E. S. R., 34, p. 450), it is stated that during 1915 the damage which it caused was more severe than ever before noticed. "By June 25 first and second stage larvæ were abundant in all the flowers and on the pods, and by July 5, when nearly all the larvæ were large, over 60 per cent of all the pods were more or less severely damaged by them. In nearly all cases the pods nearest the base of the plants, that is the earlier ones, were almost undamaged, while those near the top were so severely attacked that in many cases the flower dried up without setting any pod, while those pods which did start were small, deformed, and contained no seed at all.

"Most of the larvæ were feeding quite openly on the pods, only a few being hidden by the remains of the flower, and specimens examined during the night were found to be as active then as during the daytime. At this stage it would be possible to kill a large percentage by spraying. On July 7 there was an extremely heavy, almost tropical rainstorm, yet immediately after it quite a large number of larvæ were still feeding openly on the pods, chiefly on the lower surfaces. In the first fortnight in July nearly all the larvæ descended, but a few fed ones were found on till the end of July."

Notes on its natural enemies and host plants are included.

Four new species representing the genera Seriocothrips, Heliothrips, Thrips, and Haplothrips are described.

The green soldier bug (Nezara hilaris), R. D. WHITMABSH (Ohio Sta. Bul. 310 (1917), pp. 519-552, flgs. 16).—This is a detailed report of studies of N. hilaris, which is recorded for the first time as causing serious damage in the Northern States, although previously reported as a pest of peaches in Georgia and of oranges in Florida. It was first noticed as a serious pest of peaches in the Northern States in 1911, when it did considerable damage along the shores of Lake Erie, especially in the vicinity of Gypsum and Port Clinton, Ohio. Attention is called to the fact that it is widely distributed in the northeastern United States and Canada, where it is quite a general feeder.

There is but one brood, the greater part of the year including the winter months being passed in the adult stage. In Ohio the eggs commence to hatch the second week in June, from which time the several stages appear until about the middle of October, when the greater part become adult. The nymphs hatch out in about 7 days, and from 49 to 75 days are required for the young to pass through the five instars before becoming adult. The young nymphs of the first instar are gregarious in their habits, but upon molting the first time lose this tendency, separating in all directions in search of food.

"Fruit when badly punctured by these insects is entirely unsalable, while fruit showing but slight injury must be placed in a lower grade. It is entirely possible that one bug from the time of hatching until harvest is capable of injuring several bushels of fruit. In badly infested orchards it was not uncommon to note an average loss of at least 3 bu. per tree. Besides the actual loss one must take into consideration the amount of extra labor involved in sorting the damaged fruit."

While a proctotrypid egg parasite, probably *Trissoleus euschisti*, is of considerable importance in checking the green soldier bug, weather conditions are a dominating factor in suppressing it.

Mercurial ointment, an effective control of hen lice, G. H. LAMSON, JR. (Jour. Econ. Ent., 10 (1917), No. 1, pp. 71-74).—Substantially noted from another source (E. S. R., 35, p. 183).

Distribution of the Ohio broods of periodical cicada with reference to soil, H. A. Gossard (Ohio Sta. Bul. 311 (1917), pp. 555-577, figs. 15).—This is a report of studies which have led the author to conclude that a definite relation exists between the distribution of the cicada broods in Ohio and the soil areas in which they occur. The subject is taken up under the headings of comparative description of soils, possible ecological factors, theories of brood formation, etc.

Aphid eggs in Texas (Lat. 30° 30'), H. C. Yingling (Jour. Econ. Ent., 10 (1917), No. 1, pp. 223, 224).—The author records the deposition of eggs in Texas in December on a dogwood stem (Cornus asperifolia) by what is thought to be Schizoneura corni.

A new tree banding material for the control of the gipsy moth, A. F. Burgess and E. L. Griffin (Jour. Econ. Ent., 10 (1917), No. 1, pp. 131-135, pls. 2).—Following tests of Raupenleim applied by means of a gun manufactured for such use, the Bureau of Entomology has conducted investigations in cooperation with the Bureau of Chemistry of the U. S. Department of Agriculture which have led to the preparation of a quite satisfactory banding material. This consists of a high boiling neutral coal-tar oil having a density of about 1.15 at 20° C., a soft coal-tar pitch, rosin oil of the grade known as firstrum "Kidney" oil, and ordinary commercial quicklime, directions for the preparation of which are given. This material is considerably cheaper than any successful banding material now on the market.

"Pound for pound the tree-banding material will cover about two-thirds as many lineal feet as tree tanglefoot, but as the trees do not have to be scraped before applying the former band, the labor is reduced, so that a large saving is made by using this material. The bands remain on the trees during the winter and can be moistened with turpentine in the spring so that they will be effective for two seasons."

The present status of the gipsy and brown-tail moths in Connecticut, I. W. Davis (*Jour. Econ. Ent.*, 10 (1917), No. 1, pp. 193-195).—A brief review of the present status of these pests in Connecticut.

Crambid moths and light, G. G. AINSLIE (Jour. Econ. Ent., 10 (1917), No. 1, pp. 114-123. figs. 2).—This study is based upon collections made at light at Nashville, Tenn., during the summer of 1915. At least 14 species of Crambinæ were found to occur at that place, although the greater bulk of the material consisted of Crambus teterrellus, a very common and widely distributed species on which the data presented are based and to which the conclusions drawn directly apply. The author has been unable to determine what meteorological condition determines their attraction to light, but finds that it does not depend on temperature.

The studies have led to the conclusion that, so far at least as this species is concerned and very probably with all crambids, neither trap lights nor poisoned baits can be used successfully under normal conditions to reduce the number of these very common and secretly injurious insects.

"Side injury" and codling moth control, E. P. Felt (Jour. Econ. Ent., 10 (1917), No. 1,  $pp.\ 60-66$ ).—The term "side injury" is limited in this paper to the characteristic blemish produced by late-hatching codling moth larvæ entering the smooth side of the apple, running just under the skin a circular gallery with a radius of about  $r_{\rm ls}^{\rm l}$  in. and then in a few days deserting this initial point of injury and usually migrating to the blossom end. This blemish, which is frequently marked by a red or reddish-brown discoloration, was the cause of serious loss in western New York in 1915, as high as 20 per cent of such injury often being found in sprayed orchards. The experimental work of 1916, here reported upon, is in continuation of that of 1915, previously noted (E. S. R., 36, p. 855).

The variation in the percentage of wormy apples appears to be affected more by the size of the crop than the number of sprayings, and there is a fairly constant ratio between the total wormy fruit and the apples showing side injury. "Generally speaking, the development of side injury is conditioned upon the deposition of numerous eggs after the apples have become an inch or so in diameter and smooth enough so as not to repel the parent moth. We are satisfied that by far the greater benefit comes from the spraying just after blossoming, and that the side injury is in general proportional to the infestation of the orchard."

Recent antimosquito work in Connecticut, W. E. Britton (Jour. Econ. Ent., 10 (1917), No. 1, pp. 109-111).—A brief statement of the work carried on in Connecticut. See also the work noted on page 255.

The influence of salinity on the development of certain species of mosquito larvæ and its bearing on the problem of the distribution of species, F. E. Chidester (New Jersey Stas. Bul. 299 [1916], pp. 3-16, figs. 6).—From field records and laboratory experiments it is concluded that the distribution of the two dominant species of the salt-marsh mosquitoes in New Jersey is in part dependent on the salinity of the water. The fresher waters seem to bring out the brown salt-marsh mosquito (Aedes cantator), while the marsh pools with slightly higher salinity seem to be more favorable for the development of A. sollicitans.

Aside from its value as a means of bringing fish to the pools and providing means of quickly draining some areas, ditching is of importance in bringing salt water to increase the salinity of permanent pools, thus rendering them salt enough in some cases to retard and in some cases to check completely the development of the mosquitoes. It is suggested that there is a possibility that the incoming tide may drown the mosquito larvæ by the rise and fall of its waves as they advance.

See also a previous note (E. S. R., 36, p. 255).

A biological study of the more important of the fish enemies of the salt-marsh mosquitoes, F. E. CHIDESTER (New Jersey Stas. Bul. 300 (1916), pp. 3-16, pl. 1, figs. 2).—This is a report of studies commenced September 19, 1914, and carried on for more than a year.

The barred killifish (Fundulus heteroclitus) was found to be the greatest natural enemy of the salt-marsh mosquito and also to eat many green-head flies. "F. heteroclitus captures larvæ, pupæ, and adults of the mosquito, eating as many as 50 a day and killing many more. The vast hordes of fishes which migrate to the shallows and even into almost fresh water render the species especially formidable. The number of enemies of the mosquito which are eaten by F. heteroclitus is negligible and is more than compensated for by the great preponderance of mosquitoes in the diet of the fish. The ease with which Fundulus may be artificially fertilized and the remarkable vigor and resistance of the young embryos make the stocking of pools and streams with this species a simple matter."

A list of 19 references to the literature relating to the subject is appended. Results of ten years of experimental wheat sowing to escape the Hessian fly, G. A. Dean (Jour. Econ. Ent., 10 (1917), No. 1, pp. 146-162, flg. 1).—This is a summary of work conducted at the Kansas Experiment Station, much of which is presented in tabular form. In that State the most important steps in the control of the Hessian fly are (1) early, deep plowing of the stubble, (2) proper preparation of the seed bed, (3) destruction of all volunteer wheat, (4) delay in sowing until the fly-free date, and (5) cooperation.

Wind as a factor in the dispersion of the Hessian fly, J. W. McColloch (Jour. Econ. Ent., 10 (1917), No. 1, pp. 162-170, flg. 1).—This deals with observations made at the Kansas Experiment Station which show that wind is an important factor in the distribution of the Hessian fly. At the place where many of the observations were made the flies were being carried up over the hills and into the wheat fields lying on the other side in the Blue River Valley. The fact that the flies were uninjured on reaching the screens would indicate that they could be carried much greater distances. The relatively large number of flies caught on the small screen area at 2 miles is indicative of the possible magnitude of their flights.

This work shows that cooperation must be practiced over large areas and that the individual grower can not be promised immunity from injury even if he does prepare a good seed bed and plants late. All stubble fields and volunteer wheat fields must be plowed under early in the fall, as they are the greatest sources of infestation.

The protection of dairy cattle from flies, E. N. Cory (Jour. Econ. Ent., 10 (1917), No. 1, pp. 111-114).—Several complaints that butter made at the Maryland Experiment Station was very perceptibly tainted with the coal-tar odor where proprietary coal-tar products had been used in protecting cattle from flies led to the preparation of a pine-tar creosote emulsion which left no such taint. This was made by dissolving § 1b. of caustic soda, 98 per cent pure, in a known quantity of water for every gallon of pine-tar creosote, and then diluting with cold water to the desired strength.

In tests made of 1 to 5 per cent emulsions it was found that the 3 and 5 per cent emulsions killed all flies that were thoroughly wetted. The 3 per cent emulsion was the most effective minimum strength, its protection being fully effective for one day, and there was considerable protection afforded for two and even three days. The cost of spraying was less than 0.5 ct. per cow per application.

The radish maggot and screening, P. J. Parrott (Jour. Econ. Ent., 10 (1917), No. 1, pp. 79-81).—Experiments carried on at the New York State Station for the past three years show that, as with the seedlings of late cabbage (E. S. R., 35, p. 855), satisfactory results may be obtained from screening beds for the protection of radishes. Cheesecloth when properly attached affords complete protection from root maggots and according to the fineness of the mesh reduces to a more or less extent injuries by the flea-beetle, both of which pests when abundant may destroy as well as retard growth.

A chemical feeding analysis of white grubs and May beetles (Lachnosterna) and its economic application, J. J. Davis (Jour. Econ. Ent., 10 (1917), No. 1, pp. 41-44).—The advantages of pasturing hogs on grub-infested land are summarized as "eradication of grubs which might otherwise destroy the crops planted on the ground; value of the grubs as hog feed, which is comparable with feeds costing \$25 to \$35 per ton; and value of the manure distributed over the land, which has a money value, according to the experts of the Federal Bureau of Animal Industry, of \$3.29 per ton."

The spinach carrion beetle (Silpha bituberosa), R. A. COOLEY (Jour. Econ. Ent., 10 (1917), No. 1, pp. 94-102, pl. 1).—This little-known pest has at times been very abundant and injurious to sugar beets in the Yellowstone Valley of Montana,

The injuries by both the larvæ and adults take place mainly early in May, while the plants are still very small and before the work of blocking and thinning has been done. In Montana it is a source of injury to the sugar beet only, but has been reported by Fletcher (E. S. R., 10, p. 866) as also injuring spinach, squash, pumpkin, etc. Both adults and larvæ have been found to feed upon Monolepis nuttalliana and Solanum triflorum, and the adults only on alfalfa. It occurs from northern Kansas northward to Alberta and Saskatchewan, but does not appear west of the main divide of the Rocky Mountains except in the State of Idaho.

At Bozeman, Mont., there is but one brood per year, and the winter is passed by the adults buried in the soil. The eggs are laid, preferably in moist soil, as deep as 2 in., oviposition occurring as early as March 15 and the number laid by an individual in confinement running as high as 75, with an average of 39. The incubation period was found to vary from 3 to 6, with an average of 4.76 days, and the larval period from 20 to 33 days. The larvæ prefer to feed during the night and remain in hiding in the soil during the day. Both the adults and larvæ feed from the edges of the leaves and injured plants present a characteristic appearance. When full grown the larvæ burrow into the soil to a depth of from 1 to 2 in. and construct an oval cell in which to pupate. The period in the soil is about 25 days and the pupal period about 18 days.

In control work, poisoned-bran mash, prepared by the usual formula, scattered among the weeds near the beet fields where the insects were present in great numbers resulted in nearly complete destruction of them.

The striped cucumber beetle, H. A. Gossard (Mo. Bul. Ohio Sta., 2 (1917), No. 4, pp. 117-120, fig. 1).—A popular summary of information on this pest.

Egg-laying habits of Diprion simile, M. P. ZAPPE (Jour. Econ. Ent., 10 (1917), No. 1, pp. 188-190).—The author reports upon oviposition observations

of this European sawfly, which was first discovered in Connecticut in August, 1914, as previously noted (E. S. R., 35, p. 53).

In captivity eggs were laid on five species of five-needle pines, on six species of two-needle pines, and on one species of three-needle pines. As many as 128 eggs are deposited by a single female, usually being placed in needles of the previous year's growth, if any are present.

Notes on the bean weevil (Acanthoscelides [Bruchus] obtectus), J. A. Manter (Jour. Econ. Ent., 10 (1917), No. 1, pp. 190-193).—A summarized account of the biology of this pest and means for its control.

The alfalfa weevil investigation, G. I. Reeves (Jour. Econ. Ent., 10 (1917). No. 1, pp. 123-131).—In reporting upon the results of investigations of the alfalfa weevil by the Bureau of Entomology of the U. S. Department of Agriculture, it is stated that five practical control measures have been developed, namely, flooding with sediment, spraying with arsenical poisons, pasturing, harrowing the stubble, and colonizing with parasites. While none of these measures is entirely perfected and not all are equally valuable, they are all useful and all are in actual use.

The clover weevil in Iowa, R. L. Websteb (Jour. Econ. Ent., 10 (1917), No. 1, p. 225).—Records indicate that the clover weevil (Hypera punctata) occurs all through southern Iowa and probably most of eastern Iowa.

The plum curculio, W. H. Goodwin (Mo. Bul. Ohio Sta., 2 (1917), No. 4. pp. 113-116, figs. 4).—A brief summary of information relating to the curculio. It is stated that during the last three seasons arsenate of lead paste at the rate of 2 to 3 lbs., with 2:3:50 Bordeaux and 2 lbs. of soft soap, was used successfully under the author's direction for preventing the injuries caused by the curculio, with no injury to the fruit or foliage.

Lime as an insecticide, Z. P. METCALF (Jour. Econ. Ent., 10 (1917), No. 1, pp. 74-78, pls. 2).—This paper relates to work at the North Carolina Experiment Station with the bean weevil and cowpea weevil in cowpeas being saved for seed.

Cowpeas were treated late in September, 1913, and left until the following spring, when they were examined. Those treated with air-slaked lime at the rate of one part to four parts of peas gave a germination of 71 per cent; those with air-slaked lime, one part to eight parts of peas, gave a germination of 48 per cent; those with crude carbolic acid at the rate of one-half and one pint per bushel gave 21 per cent germination; those with kerosene at the rate of one-half and one pint per bushel, 21.5 per cent germination; and those with carbon bisulphid, at from 15 to 30 lbs. to 1,000 cu. ft. of space, 17.5 per cent germination.

The favorable results obtained with air-slaked lime resulted in the further experiments, here reported. These have led to the recommendation that cowpeas be stored in air-slaked lime at the rate of one part lime to two parts peas by weight, at least until something cheaper and more effective can be devised for the average farmer.

In a discussion of this paper which follows, W. E. Hinds states that in a series of experiments at the Alabama College Station in which several varieties of dry cowpeas were submerged in liquid carbon bisulphid for periods ranging approximately from one minute to 1,000 hours, absolutely perfect germination resulted in all cases. Tests made have shown the reported differences in germination to be due to the varying percentage of moisture at the time of the experiment.

Problems of bee inspection, F. C. Pellett (Jour. Econ. Ent., 10 (1917), No. 1, pp. 200-203).—A discussion of the problems that must be solved by the bee inspector.

The results of apiary inspection, E. F. PHILLIPS (Jour. Econ. Ent., 10 (1917), No. 1, pp. 204-210).—A discussion of results obtained from the inspection of apiaries since the first inspection law was passed by Wisconsin in 1897.

Some new and practical methods for the control of European foul brood, E. G. Carr (Jour. Econ. Ent., 10 (1917), No. 1, pp. 197-200).—A strong colony, cessation of brood rearing in the diseased combs for a time, and good Italian stock are the three principles involved in the treatment of European foul brood without destroying the combs.

Report on Isosoma investigations, W. J. PHILLIPS (Jour. Econ. Ent., 10 (1917), No. 1, pp. 139-146, pls. 2).—This is a review of the present status of Isosoma work as conducted by the Cereal and Forage Insect Investigations division of the Bureau of Entomolgy of the U. S. Department of Agriculture.

It is stated that the injury caused by *Isosoma vaginicolum*, described by Doane in a paper previously noted (E. S. R., 36, p. 59), agrees entirely with that noted in the Eastern States, and apparently is due to the same species. Up to the present time no species has been induced to breed on any other plant than its own particular host. One of the most promising measures in the control of *I. tritici* at present in some of the Eastern States is to plow under wheat stubble as soon after harvest as is possible, prepare a fine seed bed, and sow the clover and grass in August or September instead of seeding in the wheat in the spring.

## FOODS—HUMAN NUTRITION.

Biology and the nation's food, W. J. SPILLMAN (Sci. Mo., 4 (1917), No. 3, pp. 220-225).—In this paper the author discusses certain biological problems, such as increasing the acre yield of crops and increasing the production of livestock, in their relation to the future food supply.

Bread of the future and measures taken for its utilization, SCHRIBAUX (Compt. Rend. Acad. Agr. France, 3 (1917), No. 14, pp. 407-409).—Data are reported regarding the use of barley, buckwheat, and corn in supplementing the wheat supply.

It has been found possible to make a satisfactory bread by mixing 80 per cent of wheat flour and 20 per cent of barley flour. On the contrary, the mixture of buckwheat flour with that of wheat makes a dough of poor consistency on account of the decreased quantity of gluten, and fermentation is slow and irregular. The baking in this case must be done at a lower temperature than when wheat alone is used, if a hard, crusty bread is to be avoided. The proportion of barley used may be as high as 30 per cent, but not more than 20 per cent of buckwheat can be used with good results.

On the rations of bread in the army (Compt. Rend. Acad. Agr. France, 3 (1917), No. 12, pp. 352, 353).—It is maintained that there is a large amount of waste in the bread supply of the French Army. This is due to the soiling of the bread in transportation and handling and to the fact that the hard-baked bread or biscuit is often wasted by soldiers who have bad teeth.

Some common edible and poisonous mushrooms, Flora W. Patterson and Vera K. Charles (U. S. Dept. Agr., Farmers' Bul. 796 (1917), pp. 24, figs. 23).—This contains information regarding the structure of mushrooms and gives descriptions of different mushrooms and miscellaneous fungi. Precautionary measures in the selection of mushrooms for food and recipes for the canning and drying of mushrooms and their preparation for the table are included.

Concerning copper in tomatoes, P. Carles (Rev. Sci. [Paris], 55 (1917), No. 6, p. 183).—According to the author, copper has been found in fresh tomatoes and in other fresh vegetables, but not in sufficient quantity to endanger health.

Food economics at agricultural school, Minnesota University (Hotel Mo., 25 (1917), No. 290, pp. 40-45, figs. 5).—It is stated that this institution is able to serve abundant, well-planned meals to its students at a cost of 21 cents per person per day for food materials. This is made possible by careful planning, by purchasing in quantity when prices are low, and by the use of specially planned cold-storage houses, detailed plans of which are given. Fruits and vegetables are put up in their season for winter use and bread is made from cleaned whole-wheat berries which have been ground in the coffee mill at the school. Only good cream or butter is used on the table. The cost quoted was for January, 1917.

Food [of the Labrador Eskimo], E. W. HAWKES (Canada Dept. Mincs, Geol. Survey Mem. 91 (1916), pp. 29-36).—This article gives an account of the food habits of the people and describes the methods of preparation of the foods. The diet consists largely of game (seal, walrus, whale, and reindeer), fish, eggs of wild birds, herbs, and berries.

The food supply of the United Kingdom (Jour. Bd. Agr. [London], 28 (1917), No. 11, pp. 1046-1052).—This is a brief report of a survey made by a committee of the Royal Society appointed by the Board of Trade to study the food supply of the United Kingdom. It contains data regarding the food supply before the war, the food supply in 1916, and possible methods of economizing the available food supply.

Great Britain's measures for control of food, P. C. WILLIAMS (U. S. Dept. Com., Com. Rpts., No. 101 (1917), pp. 407-410).—A brief review of the efforts of the British Government to insure the conservation, economical distribution, and increased production of foodstuffs.

The growth of rats upon diets of isolated food substances, T. B. OSBORNE and L. B. Mendel (Biochem. Jour., 10 (1916), No. 4, pp. 534-538).—In this paper the authors call attention to the fact that in an article by McCollum (E. S. R., 35, p. 472) the facts reported were essentially in harmony with their own experience in the study of the growth of white rats fed upon mixtures of isolated food substances. The results of their experiments upon certain phases of the problem are reviewed and discussed in their relation to the results of other investigators in order to make clear that their own views are not at variance with those of some other investigators in this field at the present time.

The supplementary dietary relationship between leaf and seed as contrasted with combinations of seed with seed, E. V. McCollum, N. Simmonds, and W. Pitz (Jour. Biol. Chem., 30 (1917), No. 1, pp. 13-32, figs. 14).—Earlier work of the authors has demonstrated the close resemblance of wheat, maize, and oat kernels in their dietary properties, namely, the relatively poor quality of the proteins, poor content and composition of the inorganic portion of each seed, and the inadequate supply of fat-soluble A.

The present paper presents further data regarding the lines on which successful nutrition is to be attained when the diet is derived solely from vegetable sources, the discussion being limited to the results obtained with combinations of seeds from several sources and of seeds with the alfalfa leaf. Feeding experiments have shown that the nutritive requirements for rats and swine are essentially the same and that neither species can grow satisfactorily when restricted to one of the cereal grains, although both respond in much the same way with growth and reproduction to specific modifications of the diet when restricted as to source.

The authors have been unable to make up a ration derived solely from the seeds of plants which would support normal nutrition through the growing period even though from 2 to 5 seeds of widely different varieties were employed. However, results of a very different character were secured when simple combinations of leaf and seed were fed as monotonous diets. It has been found that with wheat, oats, and maize in equal proportions both salts and fat-soluble A must be added to the ration before growth can take place, and that "it is difficult if not impossible to obtain even a moderate amount of growth over an extended period on a diet restricted to the seeds of plants."

Satisfactory protein mixtures can be had from seed mixtures, and experiments have shown also that certain seeds, such as flaxseed and millet, contain the fat-soluble A in fairly liberal amounts. "Since the water-soluble B is everywhere abundant in the seeds the cause of failure to secure growth on seed mixtures is seen to lie in the amount and character of the inorganic moiety. . . . Of the seven most important seeds from the standpoint of human nutrition and animal production only cotton seed and flaxseed contain a high total inorganic content, and in both cases the ash is very poor in three important elements, sodium, calcium, and chlorin. Since a pronounced deficiency of these elements is characteristic of all other seeds as well, no combinations of seeds will supply these elements in satisfactory amounts."

The necessary inorganic supplements may be secured in some localities through the drinking water, which would enable the animals in those localities to grow on a ration restricted to seeds.

"The leaf is distinctly different from the seed in its dietary properties in two respects: Its total inorganic content is very high, and it is especially rich in both sodium and calcium, both of which are deficient in the seeds generally. In addition the leaf of the plant is several times richer in fat-soluble A than are the wheat, oat, and maize kernels. Certain seeds approximate the value of the leaf in this substance. Hempseed is distinctly better than those just named, but flaxseed and millet seed are still richer than hempseed and may readily be incorporated in the diet in amount sufficient to meet the needs of an animal for the fat-soluble A during growth."

Feeding experiments with deficiencies in the amino-acid supply: Arginin and histidin as possible precursors of purins, H. Ackboyd and F. G. Hopkins (Biochem. Jour., 10 (1916), No. 4, pp. 551-576, figs. 6).—This paper reports the results of a large number of experiments with laboratory animals (rats). The data obtained may be summarized briefly as follows:

Removal of arginin and histidin from the diet of rats which had been previously growing on a complete amino-acid mixture resulted in a rapid loss of body weight. Restoration of the missing diamino acids to the diet resulted in renewing growth.

Restoration of arginin alone or histidin alone resulted in no loss of weight and in some cases in growth. Nutritional equilibrium was possible in the absence of one of these related protein constituents, although not in the absence of both. A reason suggested for this is that each one of them can in metabolism be converted into the other. When arginin and histidin were both removed from the food the amount of allantoin in the urine was much decreased, but when they were replaced the excretion returned to normal. The decrease was very much less when either one of these diamino acids was present alone.

When tryptophan was removed from the food no decrease of allantoin occurred, although nutritional failure was even greater than when arginin and histidin were withheld. No decrease of allantoin excretion was observed when the animals were losing weight as the result of the absence of vitamins from the diet.

In view of these results the authors suggest that arginin and histidin play a special part in purin metabolism, probably constituting the most readily available raw material for the synthesis of the purin ring in the animal body.

The influence of heavy metals on the isolated intestine, W. SALANT and C. W. MITCHELL (Amer. Jour. Physiol., 39 (1916), No. 4, pp. 355-374, figs. 14).

The respiratory process in muscle and the nature of muscular motion, W. M. Fletcher and F. G. Hopkins (*Proc. Roy. Soc.* [London], Ser. B, 89 (1917), No. B 619, pp. 444-467, figs. 8).—This lecture deals with the intramolecular oxygen and the theory of "inogen," the effects of oxygen upon muscle, lactic acid in muscle, and the heat production of muscle. From a consideration of all the data presented, the authors bring out the fact that the actual chemical changes which underlie the contraction, fatigue, and recovery of muscle are relatively simple and that the chemical changes themselves are not complex or obscure, the complexity being found only in the condition under which they occur. A bibliography is appended.

Clinical calorimetry, XIX-XXV (Arch. Int. Med., 19 (1917), No. 5, pp. 823-957).—Seven articles are presented.

XIX. The basal metabolism of old men, by J. C. Aub and E. F. DuBois (pp. 823-831, figs. 2).—The subjects of these experiments were from 77 to 83 years old and were in good health, considering their ages. The average basal heat production, as determined by calorimeter experiments, was found to be 35.1 calories per square meter of body surface per hour, which is 12 per cent below the average for men between the ages of 20 and 50. The results obtained by direct and indirect calorimetry agreed closely and the respiratory quotients were all within normal limits.

XX. The effect of caffein on the heat production, by J. H. Means, J. C. Aub, E. F. DuBois, and G. F. Soderstrom (pp. 832-839, fig. 1).—The authors review the literature regarding the effect of caffein on metabolism and report the results of calorimeter experiments on four normal men. After a preliminary period and one or two hours' observation of the subjects' normal basal metabolism, the caffein was ingested in the form of the pure alkaloid dissolved in pure water. Studies were made of the basal metabolism after the ingestion of caffein, of the respiratory quotient, of the elimination of water from the skin and lungs, of the elimination of nitrogen, and of the pulse rate. The results of the investigation are summarized as follows:

"An increase of from 7 to 23 per cent in the basal metabolism was found in four normal subjects after receiving from 8 to 10 grains of caffein alkaloid (8.6 mg. per kilogram of body weight). After taking the drug there was no significant change in the pulse rate, in the respiratory quotient, in the proportions of the various foodstuffs metabolized, or in the percentage of heat lost in the vaporization of water. The independent methods of direct and indirect calorimetry gave results which agreed within 1 per cent."

XXI. The basal metabolism of dwarfs and legless men with observations on the specific dynamic action of protein, by J. C. Aub, E. F. DuBois, and G. F. Soderstrom (pp. 840–864, figs. 8).—This paper reports the results of calorimetric observations upon five dwarfs, two legless men, and six normal (male) controls. The results are summarized as follows:

"The legless men and the dwarfs with apparently normal endocrine systems showed, in relation to their surface area, the same level of metabolism as normal men. The law of surface area holds good for men of unusual body shape.

"The dwarfs with involvement of the ductless glands and symptoms of cretinism showed a marked reduction in metabolism below the average found in normal cases, as has been reported by other authorities.

"Following the ingestion of large quantities of meat, the excretion of urinary nitrogen during the earlier hours is not an accurate index of the protein metabolism. The sulphur excretion is more rapid than the nitrogen excretion.

"The stimulation of metabolism following a large amount of meat is almost at its height two hours after the meal is eaten. The extra heat produced may amount to three-quarters of the calories in the protein metabolized, and may lead to an increase of 46 per cent above the level of the basal heat production,

"The specific dynamic action of a meal containing 24 gm. of nitrogen in the form of meat was larger in the case of a legless man and of an achondroplastic dwarf with very small arms and legs and normal trunk than in the cases of three normal controls of greater weight and greater surface area. This indicates that the intensity of the specific dynamic action is not proportional to the mass of the musculature. The true explanation of the results can not be given in the light of present knowledge. Various possible explanations come naturally to mind, such, for example, as a greater concentration of amino acids in the blood flowing to the muscles, or the presence of a liver, which, in proportion to the size of the organism, is relatively larger than the normal."

XXII. The respiratory metabolism in nephritis, by J. C. Aub, E. F. Du Bois, and G. F. Soderstrom (pp. 865-889).—This paper reports the results of studies, in the respiration calorimeter, of 10 individuals suffering from nephritis. The following are quotations from the author's summary:

"In most of the patients with greatly increased blood pressure the metabolism was higher than in the other nephritics with lower blood pressures. Most of the patients with marked dyspnea showed some increase in metabolism....

"The respiratory quotients are all within normal limits, showing that nephritics derive their energy from very much the same proportions of the various foodstuffs as do normal men. . . .

"The normal quotients found in patients with low carbon dioxid combining capacity of the plasma prove that nephritic acidosis is not caused by difficulty in oxidizing carbohydrates."

XXIII. The effect of Roentgen-ray and radium therapy on the metabolism of a patient with lymphatic leukemia, by J. B. Murphy, J. H. Means, and J. C. Aub (pp. 890-907, figs. 3).

XXIV. Metabolism in three unusual cases of diabetes, by F. C. Gephart, J. C. Aub, E. F. Du Bois, G. Lusk, and G. F. Soderstrom (pp. 908-930).

XXV. The water elimination through skin and respiratory passages in health and disease, by G. F. Soderstrom and E. F. Du Bois (pp. 931-957). As a result of these experiments the authors state that the technique of determining the water eliminated from the skin and respiratory passages of the subject in a respiration chamber is exceedingly difficult for the following reasons: Moisture will be deposited on the contents of the chamber if the humidity of the air in the chamber rises, and water will be removed which was not eliminated by the subject in the experimental period if the relative humidity of the air in the chamber falls. Over 300 experiments were made with the Sage calorimeter at an air temperature of 22 to 25° C. and a relative humidity between 30 and 50 per cent. For purposes of comparison, all experiments were excluded in which the relative humidity changed more than 10 per cent during the observation period. A table is given showing the water vaporization of different groups of subjects studied under different conditions of growth, temperature, and ventilation.

"Normal men 20 to 50 years old under the standard conditions excrete on an average 29 gm. water an hour (about 700 gm. a day) through skin and air passages, losing in this manner 24 per cent of the total heat produced. Few normal men depart more than one-tenth from this figure. All the results on groups of patients are compared with this standard figure of 24 per cent ±0.1. Boys 12 to 13 years old give figures close to the upper limit and very old men lose almost the same percentage of calories in vaporization. Dwarfs

and legless men are also close to the normal average. Cretinoid dwarfs show diminished water elimination. Typhoid patients with a rising temperature also have a decreased water output; those with a falling temperature lose an increased percentage of calories in vaporization. The water output in convalescence is low.

"Some patients with hyperthyroidism have a decreased water output; most of them lose the normal percentage of calories in vaporization. Some lose much more than normals in this manner. In pernicious anemia the water of vaporization is not affected. Cardiac and nephritic patients on the whole give figures close to the normal. There is a slight increase in dyspneic patients. Edema seems to have no effect on the water output through the skin. The results in diabetes show great variations. The average figure, however, is about the same as that obtained in normals.

"In conclusion it may be said that the output of water is very little affected in disease. When the heat production is increased the body responds and dissipates the usual percentage of calories in the vaporization of water. When it is necessary to get rid of unusual amounts of heat the percentage lost in vaporization is increased."

#### ANIMAL PRODUCTION.

Commercial feeding stuffs, J. P. Street et al. (Connecticut State Sta. Rpt. 1916, pt. 3, pp. 147-184).—This is a report of the State feed inspection, including analyses of cottonseed meal, linseed meal, wheat bran, wheat middlings, red dog flour, rye middlings, buckwheat middlings, corn gluten meal, corn gluten feed, hominy feed, dried brewers' grains, malt sprouts, dried distillers' grains, dried beet pulp, meat scrap, tankage, bone, coconut meal, salvage wheat, cracked corn, alfalfa meal, beans, bread crumbs, and mixed, proprietary, and poultry feeds.

[Animal husbandry work at the Crookston substation] (Minnesota Sta., Rpt. Crookston Substa., 1910-1916, pp. 83-87).—In an experiment during the winter of 1913-14 beef cattle were maintained in prime condition in a straw shed. In this test dry shock corn was equal to corn silage as a supplement to millet and timothy hay and ground oats and barley. There was some waste from unconsumed cornstalks, whereas all the silage was eaten. Difficulty was experienced in feeding silage out of doors in cold weather.

In a test during the winter of 1913-14 it was found that sheep did not relish warm water.

Ground flaxseed was compared with tankage as a protein supplement to barley, corn, and oats for pigs. The tankage proved distinctly superior to the flaxseed, and the results indicated that the latter is not a practical feed for swine.

Wet-mash feeding was compared with dry-mash feeding for laying hens in the winter of 1913-14. The wet-marsh lot laid slightly more eggs at a smaller cost per dozen than the dry-mash lot. In later years, however, the dry-mash method gave better results at a less labor expenditure than the other method. Wet mash proved superior to dry mash for young chicks, especially during the first week of the chick's life. In a fattening test with three-months-old cockerels, Barred Plymouth Rock cockerels gained 2 lbs. each in three weeks as compared with 1.16 lbs. for Leghorn cockerels.

The results of egg preservation experiments in 1913 showed that a solution of sodium silicate and water (1:5) is unnecessarily strong, a dilution of 1:10 giving the best results. Eggs stored in limewater (1 lb. of lime to 5 gal. of water) kept in excellent condition, except that the bottom layer of eggs had a

slight flavor of lime. Similar results were secured in tests in 1915. In 1915 eggs packed in boxes in powdered peat and in common salt evaporated considerably in 6.5 months' storage, and the flavor was only fairly good.

[Feeding experiments with beef cattle, brood sows, and work horses] (Minnesota Sta., Rpt. Duluth Substa., 1916, pp. 7-9, 10, 11).—In 1916 young beef animals were pastured without extra feed on range a part of which was tame grass pasture. Three of the yearlings were on grass 49 days and seven 127 days. They made an average daily gain of 1.59 lbs. per head.

Brood sows on pasture from June to September, inclusive, slightly increased in weight when receiving \( \frac{1}{3} \) lb. of grain per 100 lbs. live weight, whereas before and after the pasture period they consumed 1 lb. of grain per 100 lbs. live weight.

Six work horses were pastured at night on stump-land pasture from June to August, inclusive. During the three months the night pasture resulted in a saving of 12 lbs, of hay and 1 lb, of grain per head daily.

In a test of a self-feeder for pigs on a ration of tankage shorts, ground barley, and skim milk, 13 pigs made an average daily gain from June 15 to October 15 of 118 lbs. per head at cost for grain of \$4.69 and a profit of \$11.80.

A feeding trial with a litter of fall pigs is also noted.

The theory of correlation as applied to farm-survey data on fattening baby beef, H. R. Tolley (U. S. Dept. Agr. Bul. 504 (1917), pp. 14).—This bulletin gives the results of an experiment in applying the theory of correlation to the study of some of the data obtained by the Office of Farm Management in a survey of corn-belt farms upon which baby beef was being fattened for market, the details of which have already been noted (E. S. R., 35, p. 668). The factors here considered are the profit or loss per head, the weight, value per 100 lbs., value of feed consumed per head, cost at weaning time, and date of sale. Coefficients of correlation were computed and tabulated for every pair of these factors and used as a measure of the relationship existing between them.

The author concludes that "data such as those obtained by farm management surveys can be analyzed very thoroughly by the use of the correlation coefficients. It is generally known before the analysis is attempted which factors are causal and which resultant, and consequently there should be very little difficulty in interpreting the coefficients correctly. The coefficients of net correlation afford a very good means of determining the net effect of each of several factors bearing upon a result, or of eliminating the effect of other factors when it is desired to find the true relationship existing between any two.

"Although it is not possible to give a definite concrete meaning to correlation coefficients, they are very concise relative measures of the degree of relationship existing between the factors being studied. They therefore give the investigator a single index which will show what, by the ordinary tabular method, it takes a whole table to show. While properly constructed tables will show whether or not any relationship exists between factors, it is a difficult matter to determine which of two causes, say, has the greater effect on the result, and it is impossible, without a large number of records and a great amount of sorting and tabulation, to separate all the factors being considered in a study and find the effect that each one would have had if the others had not been present, or if they had been constant throughout the investigation.

"If the gross coefficients of correlation between every pair of factors have been determined, it is possible to find these relationships by simply substituting in the formula for determining a net coefficient from the gross coefficients, without any further reference to the records themselves. This method should be especially useful if only a limited number of records or observations are

available, for it does away with the necessity of sorting into many groups, with the consequent falling off in the reliability of the averages obtained."

The analysis of the data on fattening baby beef animals indicates that "for the herds considered, the cost of producing the calves and carrying them until weaning time was by far the most important factor in determining the profit. There was no connection between the cost at weaning time and any of the other factors, for the calves which were produced cheaply were seemingly just as good feeders and brought just as good a price per pound as the more expensive ones. The weight at which the calves were sold and the date of sale had very little effect on the profit, except for the fact that in the two years of the records the price was higher in the latter part of the summer, at the time when the heavier calves were put on the market. The calves which consumed the heaviest ration sold at higher prices than the others, but did not return a correspondingly greater profit, as the advanced price scarcely offset the extra value of feed consumed."

Steer feeding.—X, Winter steer feeding, 1913-14, J. H. SKINNER and F. G. King (*Indiana Sta. Bul. 178* (1914), pop. ed., pp. 8).—A brief summary of experiments already noted (E. S. R., 33, p. 371).

Sheep feeding.—IV, Fattening western lambs, 1913-14, J. H. SKINNER and F. G. King (*Indiana Sta. Bul. 179* (1914), pop. ed., pp. 8).—A brief summary of experiments already noted (E. S. R., 33, p. 374).

[Feeding experiments with pigs in Minnesota] (Minnesota Sta. Rpt. 1916, pp. 45, 72).—In a comparison of hand feeding with self feeding, 100 pigs in ten lots were fed solely on grain rations consisting of various mixtures of shelled corn, shorts, tankage, ground barley, and linseed meal. In every case the self-fed pigs made larger daily gains than those fed twice daily by hand.

Rape pasture supplemented with 2, 3, and 4 per cent shelled-corn rations gave average daily gains per pig of 0.61, 0.81, and 0.93 lbs., respectively. Valuing corn at 75 cts. a bushel, and pasture at \$10 an acre, the actual feed cost per pound of gain was 4.6, 4.46, and 4.81 cts., respectively.

Results at the Crookston substation are noted on page 268 and below.

The fall litter of pigs, W. Dietbich (Minnesota Sta., Rpt. Crookston Substa., 1910-1916, pp. 93-95; Minnesota Sta. Rpt. 1916, p. 72).—Suggestions are given for the successful raising of fall pigs under northern Minnesota conditions.

Twelve pigs born about September 1, 1915, were weaned and put on feed November 22 and fed until the following May. The rations consisted of barley, oats, and tankage, to which corn was added at the beginning of the eleventh week, and a little rye during the last week of the test.

In addition to the above feeds and water these pigs had a small quantity of a 1 per cent solution of concentrated lye, and were also given access to ground limestone and bone meal. At eight months these pigs averaged 255 lbs. each. They required 5.42 lbs. of feed per pound of gain.

[Clover pasture for hogs] (Minnesota Sta., Rpt. Duluth Substa., 1915, pp. 5, 6).—In a feeding test with three sows during July and August, it was found that dry brood sows may be maintained on good clover pasture with practically no grain if they are mature, but that a light grain ration is desirable if they are growing.

[Report of the] Kansas state live stock registry board (Kansas Sta. Insp. Bul. 1 (1915), pp. 239).—This gives data as to the effect of the stallion license law on the horse-breeding industry of the State, a report of the sixth annual meeting of the Kansas Horse Breeders' Association, a summary of the results secured at the Kansas Station in experiments upon developing draft colts (E. S. R., 36, p. 172), and lists by counties and breeds of stallions licensed in the State during 1915.

Feeding for egg production, P. Moore (*Idaho Sta. Circ. 3* (1916), pp. 6).—Results are given of a feeding experiment which began November 1, 1914, and ended October 31, 1915, with three pens of 30 White Leghorn pullets each. The following rations were fed: Pen 1, a scratch feed of wheat, oats, and barley (15:2:2), and no mash; pen 2, a scratch feed of wheat, peas, oats, barley, Kafir corn, millet, sunflower seed, and buckwheat (12:2:3:2:1:1:5:05:1), and a dry mash of bran, shorts, corn meal, wheat meal, fish-meat meal, and charcoal (2:2:1:1:2:1); and pen 3, the same as pen 2 except that corn was substituted for peas in the scratch mixture, and the proportion of oats and barley slightly decreased. All the fowls were given green feed in some form throughout the year.

The fowls in pen 1 failed to keep in flesh, and those in pen 3 maintained more uniform weights than those in pen 2, indicating that corn is essential in a well-balanced poultry ration. During the year pen 1 laid 739 eggs,  $66\frac{1}{3}$  per cent of which were under 2 oz. in weight; pen 2 laid 3,486 eggs, 5.5 per cent of which were under 2 oz.; and pen 3 laid 3,938 eggs,  $6\frac{2}{3}$  per cent of which were under 2 oz.

Notes are given on balancing poultry rations.

Poultry feeding test, home-grown versus purchased feeds (Minnesota Sta., Rpt. Duluth Substa., 1916, p. 11; abs. in Minnesota Sta. Rpt. 1916, p. 79).—Two pens of 40 White Leghorn hens each were fed during January, February, and March, 1916. In addition to other feeds the hens in the purchased-feeds lot received corn and meat scrap and those in the home-grown-feeds lot, barley, milk, and peas. The former lot laid 476 eggs and the latter 499 eggs within the three months.

## DAIRY FARMING—DAIRYING.

The dairy industry in Argentina, P. Berges (An. Soc. Rural Argentine, 50 (1916), No. 2, pp. 81-131, figs. 21; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 9, pp. 1357-1362).—The author treats of the present state of the dairy industry of Argentina, sanitary inspection of milk and butter, testing of milk intended for human consumption and butter making, economic returns of the dairy industry, a comparison of the dairy industry of Argentina with that of other countries, and plans for the development of the dairy industry in Argentina.

Net value of pasturage (Minnesota Sta., Rpt. Duluth Substa., 1915, pp. 7, 8).—Five acres of pasture land seeded after clearing maintained an average of three cows and two heifers for 30 days the first year after seeding, during which time the total returns of beef and milk fat amounted to \$5.33 per acre. It is estimated that this pasture land gave a total return of \$10 per acre for the whole season.

[Pasturing experiments with cows at the Duluth substation] (Minnesota Sta., Rpt. Duluth Substa., 1916, p. 7).—Continuing the work noted above, 4 cows were pastured on the same 5-acre tract for 137 days in the summer of 1916, receiving in addition 1 lb. of grain to each 4 lbs. of milk produced. During this time the cows produced 497.83 lbs. of milk fat. Valuing the milk fat at 33 cts. per pound and the grain fed at \$25.95, the pasture was worth \$13.83 per acre for the season.

[Record of dairy herd at the Grand Rapids substation] (Minnesota Sta. Rpt. 1916, pp. 75, 76).—Data are tabulated showing the results of five years' work in breeding up a herd of common cows by the use of pure-bred Guernsey sires.

It is noted that the average annual milk production per cow increased from 5,300.9 lbs. in 1911 to 5,721.2 lbs. in 1915. During this time the average fat content of the milk increased from 4.27 to 4.9 per cent, and the annual milk-fat production per cow from 226.6 to 279.8 lbs.

Studies in milk secretion, I, II, J. Hammond and J. C. Hawk (Jour. Agr. Sci. [England], 8 (1917), No. 2, pp. 139-153, figs. 2).—Two articles are presented.

I. The effect of nutrition on yield and composition (pp. 139-146).—Using well-fed goats, a study was made of changes in the yield and composition of the milk which followed a sudden change in nutrition. The changes in nutrition were brought about by the administration of phlorizin, together with the control of the food supply.

When food was withheld from goats for a short time and then an abundant supply given them, the amount of milk and fat secreted was decreased and the percentage of fat increased, due to the lowering of the plane of nutrition. When food was withheld, phlorizin injected, and a few days afterwards a plentiful supply of food given, results similar to those above, yet much more marked, were secured. The return to normal production was very gradual, indicating that phlorizin has a rather long-continued action. In two cases out of the three, the fat percentages at the end of the experiment was below that at the beginning, although the milk yield had not returned to normal. In a third series of experiments phlorizin was injected into goats under normal conditions of feeding. There was great variation in the effects on different individuals, the results indicating that it was the goats in the poorest state of nutrition that showed a diminution in milk yield as a result of the injection of phlorizin.

II. The relation of the glands of internal secretion to milk production (pp. 147-153).—The effect of pituitary extract on the milk flow of animals under conditions of reduced nutrition was studied. Goats were injected with 1 cc. of pituitary extract per head daily during a period of sudden change from a high to a low condition of nutrition. This change was brought about by withholding food or by the injection of phlorizin as in the experiments noted above.

The results indicate that the amount of milk produced by the action of pituitary extract varies with the state of nutrition. It was found that the variation in yield as a result of pituitary injections was not so great as the normal daily variations. The percentage of fat in the milk produced within half an hour after the injection of pituitary extract rises with the fall in nutrition, as it does in the case of normal nilk.

A study was made of the effect of the injection of adrenalin into lactating goats. In these tests an average of 6 cc. of a 1:1,000 solution of adrenalin chlorid was injected into each goat on alternate days after the morning milking, the goats being milked again after an interval of half an hour. On the other days sterilized water was injected in place of the adrenalin. The injection of the adrenalin had no immediate effect on the amount of milk secreted, but there was a secondary effect causing a decrease in the amount of milk produced for a day following the injection. The percentage of fat in the milk was increased, but the amount of fat was somewhat decreased following the injection of adrenalin.

The results of these experiments indicate that the rate of milk flow is very susceptible to changes in the sugar metabolism of the animal.

On the fat of Egyptian buffalo milk, G. Hogan and E. Griffithes-Jones (Dept. Pub. Health [Egypt], Hyg. Inst. Pub. 5 (1916), pp. 3).—Analyses are given of 69 samples of buffalo milk fat, each sample being representative of the mixed milk of a complete milking of five or six buffaloes.

The maximum figures obtained were Reichert-Meissl value 37, Polenske value 2.8, saponification value 235, Hübl's iodin value 39.7, and butyro-refractometer reading at 40° C. 44. The corresponding minimum figures were 24.5, 1, 218, 23, and 40.4, and the average, 31.2, 1.5, 229, 31.4, and 42.5, respectively.

Variations in the composition of human milk during the first eleven days after parturition, F. S. Hammett (Jour. Biol. Chem., 29 (1917), No. 2, pp. 381-390).—A study is reported of variations observed in the chemical composition of human milk during the first 11 days after parturition. The milk production of eight women was studied.

There was an increase in the amount of fat and lactose during the period, while there was a falling off in the production of protein. It is stated that the protein mechanism is apparently the best regulated, and is less dependent upon the factors controlling the fat and lactose production than they are on each other. For the single constituents there was found to be a production plane uniform for the individual subject. This plane of production is apparently fixed for the individual, independent of the plane of nutrition, and dependent upon the individuality. An increase or decrease in the lactose production was usually accompanied by a change in the opposite direction in the percentage of fat and protein.

A bibliography is included.

A new defect in milk caused by Bacterium lactis aerogenes, M. Duggeli (Ztschr. Gärungsphysiol., 5 (1916), No. 5, pp. 321-340; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 9, pp. 1363, 1364).—Attempts were made to discover the cause of a bitter taste and typical rancid smell in bottled milk produced under sanitary conditions in a herd of 36 cows. No bitter substance could be discovered in the milk, but it was found that the defect was due to one cow with a diseased udder. A bacterium belonging to the group B. lactis aerogenes, and thought to be the cause of the defect in question, was isolated from specimens of the mixed milk. This bacterium gave rise to an abnormal smell and taste, possessed the property of making glucose bouillon very ropy, and prevented the coagulation of milk in the presence of B. güntheri. It lost the characteristic taste and smell when cultivated on lactose agar, but these reappeared in part when the organism was cultivated in a suitable medium.

An epidemic of septic sore throat due to milk, E. C. Rosenow and C. L. V. Hess (Jour. Amer. Med. Assoc., 68 (1917), No. 18, pp. 1305-1307, fig. 1).—An account is given of an outbreak of severe sore throat in Galesville, Wis., involving about 200 persons, the cause of which was traced to three cows on one farm, affected with mastitis.

Septic sore throat, G. W. Henika and I. F. Thompson (*Jour. Amer. Med. Assoc.*, 68 (1917), No. 18, pp. 1307-1309, fig. 1).—This is an epidemiologic study of the milk-born epidemic noted above.

Spring conditions affecting the cream producer, H. A. RUEHE (Illinois Sta. Circ. 195 (1917), pp. 4, fig. 1).—Suggestions are given for overcoming some of the more common troubles that affect the production of high-grade cream under spring conditions.

Manufacture and composition of Bulgarian cheeses, A. S. ZLATAROFF (Ztschr. Untersuch. Nahr. u. Genussmtl., 31 (1916), No. 12, pp. 387-394; abs. in Internat. Inst. Agr., [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 9, pp. 1364-1367).—A description is given of Bulgarian and Kaschkawal cheeses, which, it is stated, make up the bulk of the total output of cheese in Bulgaria. Information is included on the importance of cheese making in Bulgaria.

Rennet substitutes (N. Y. Produce Rev. and Amer. Cream., 43 (1917), No. 22, pp. 906, 908, 909).—A brief symposium is given on the use of rennet sub-

stitutes in cheese making. Results of cheese making experiments at the Finch dairy station in Ontario, Canada, in which several commercial brands of pepsin and rennet were tested, and notes on the use of pepsin in cheese making are summarized by J. A. Ruddick and G. H. Barr. In these experiments the pepsin cheese was found to be as good in texture and slightly better in flavor after nine months' storage than that made from rennet. The relative value and milk-coagulating power of the various brands tested are tabulated.

#### VETERINARY MEDICINE.

American Veterinary Medical Association.—Report of committee on diseases, J. R. Mohler (Jour. Amer. Vet. Med. Assoc., 50 (1917); No. 7, pp. 895-904).—This report consists of a brief statement regarding the status of the more important diseases which threaten the live-stock industry of the United States, including hemorrhagic septicemia, hog cholera, foot-and-mouth disease, dourine, tuberculosis, swamp fever, contagious abortion, and influenza.

Sixteenth biennial report of the State Live Stock Sanitary Commission of Michigan for the years 1915 and 1916, G. W. Dunphy and E. T. Hallman (Bien. Rpt. State Live Stock Sanit. Com. Mich., 16 (1915-16), pp. 31, pls. 4).— This report deals with the work of the years 1915 and 1916 including the occurrence of and control measures against tuberculosis, hog cholera, contagious abortion, hemorrhagic septicemia, rabies, and anthrax.

Annual administration report of the civil veterinary department in Baluchistan for the official year 1915-16, J. G. CATTELL (Ann. Admin. Rpt. Civ. Vet. Dept. Baluchistan, 1915-16, pp. 16).—This report deals with veterinary instruction, treatment of disease, including the occurrence of and work with the contagious diseases of animals during the year, breeding operations, etc.

Annual administration report of the civil veterinary department, Madras Presidency, for 1914-15 (Ann. Admin. Rpt. Civ. Vet. Dept. Madras, 1914-15, pp. 26, pl. 1).—This report includes accounts of the occurrence and treatment of diseases of live stock in the Madras Presidency during 1914-15.

Studies in pneumonia.—II. Various methods of determining the bactericidal action of substances in vitro and their relation to the chemotherapy of bacterial infections, J. A. Kolmer, S. Solis-Cohen, and G. D. Heist (Jour. Infect. Diseases, 20 (1917), No. 3, pp. 293-312).—The authors have carefully studied, and modified in some instances, the Rideal-Walker and Hygienic Laboratory methods, the centrifuge method, pipette method, combined in-vitro-vivo method, antiseptic method, and plating method.

It is concluded in general that in-vitro bactericidal tests are probably of value in chemotherapeutic studies, this being based on the general observation that substances most parasiticidal in vitro also show this quality in marked degree in vivo. "In-vitro tests should be conducted when possible with the microparasite causing the malady under study, as the object of chemotherapy should be the production not only of polybacteriotropic and polyprotozootropic chemicals but also of monotropic substances for a definite microparasite. In the absence of a pure culture of the particular microparasite under study, a closely allied species may be used. . . . It is highly important to adopt a definite technique and adhere to it in every detail in conducting these tests, because different methods yield varying results, depending mainly on whether the substance excels as a bactericide (killing quickly in high concentration, but losing rapidly in bactericidal power in low concentration) or as an antiseptic (retaining bactericidal power to a better extent in low concentration)."

The procedures are described in detail, discussed, and some experimental data submitted. See also a previous note by Kolmer, Schamberg, and Raiziss (E. S. R., 36, p. 679).

The differentiation of the paratyphoid-enteritidis group, I, E. O. Jordan (Jour. Infect. Diseases, 20 (1917), No. 4, pp. 457-483).—The cultures of bacilli belonging to the paratyphoid-enteritidis group that were examined by the author and are here considered fall into four subdivisions, namely, Bacillus paratyphosus A, B. paratyphosus B, B. suipestifer, and B. enteritidis.

The enzyms of the tubercle bacillus, H. J. Corper and H. C. Sweany (Jour. Biol. Chem., 29 (1917), No. 2, pp. XXI, XXII).—It is noted that tubercle bacilli, both human and bovine, possess autolytic enzyms, as is indicated by the liberation at incubator temperature of noncoagulable nitrogen and aminoacid α-nitrogen after the organisms have been killed by toluene and chloroform. The bacilli themselves, or autolyzates therefrom, also possess a trypsin-like enzym capable of cleaving proteins in alkaline solution, a weak pepsin-like enzym active in acid solution, an erepsin-like enzym capable of cleaving peptone in acid solution, a nuclease which acts on nucleic acid, and a urease. No starch-hydrolyzing or saccharose-inverting enzyms or enzyms capable of digesting elastic tissue prepared from lamb's lung or connective tissue prepared from tubercles could be demonstrated by the methods used for detecting these enzyms. It is indicated that the demonstration of the latter enzyms must be by indirect methods, and the results are therefore not conclusive.

The immune reaction to tuberculous infection, R. Weil (Jour. Amer. Med. Assoc., 68 (1917), No. 13, pp. 972, 973, figs. 2).—From some data obtained by suspending the uterus from a sensitized animal in Locke's solution and determining the effect of the antigenic substance on its muscular contractions, the author indicates that "it is clear that these antibodies must be considered to be cellular or 'sessile,' since it is only on this theory that the response of the isolated organ can be explained. It is not to be supposed that the uterine cells are the only ones of the body which contain the specific antibodies. In fact, it is highly probable that many, if not all, of the tissues of the body are similarly altered by tuberculous infection. . . . If this be the case, it seems highly probable that the various types of altered reaction, . . . whether local or general, are to be explained on the basis of cellular sensitization to the agent of the disease and to its products. The details of the mechanism of these reactions, as well as of the partial immunity of the infected animal, will perhaps be found to correspond to analogous conditions in general anaphylaxis."

The treatment of experimental tuberculosis in guinea pigs and rabbits by taurin, alone and in combination with gold chlorid and sodium oleate, M. Takeoka (Jour. Infect. Diseases, 20 (1917), No. 4, pp. 442-456).—Experimental data of a study of the curative value of taurin alone or in combination with a colloidal mixture of sodium gold chlorid and sodium oleate in experimental tuberculosis in guinea pigs and rabbits are reported. The guinea pigs were infected with either bovine or human strains of the organisms, the results being similar in both cases.

In general the control animals died before any of the treated animals, and whereas the controls lost weight almost uniformly, the treated animals gained. The majority of the treated animals were killed for observation many days after the controls had died, and the contrast in the extent of visible tuberculosis was marked. While the process was found to be advanced in the controls, it was arrested and in some instances apparently cured in the treated animals.

Rabbits were infected with intraperitoneal or intravenous injections of the bovine strain. The treatment was carried out by intravenous injections of

taurin alone, the results being similar but even more marked than in the experiments with guinea pigs. Histologic examination of the organs in treated animals showed arrested tubercles, absence of caseation, disappearance of the tubercle bacilli and lesions, and evidence of repair by connective-tissue in growth. The controls showed advancing lesions, caseation, and numerous bacilli. A number of the treated animals showed slight evidences of tuberculosis, but in no inconsiderable number were the tissues essentially normal microscopically.

Suppuration in cattle and swine caused by Bacterium pyogenes, A. R. Ward (Cornell Vet., 7 (1917), No. 1, pp. 29-42, pl. 2).—This discussion of the general characteristics of the lesions and of those found in swine and in cattle is based upon investigations and an extensive review of the literature in connection with a list of 15 references appended.

"Bacillus pyogenes differs from the common pyogenic organisms in that it possesses the peculiarity, under certain conditions, of stimulating the proliferation of connective tissue to form tumor-like masses similar to granulation tissue, and of subsequently inducing the necrotic changes leading to the formation of an abscess within the newly formed tissue. This type of suppuration as a consequence of the preliminary tissue proliferation follows a slow chronic course. In this peculiarity the development of the lesions of B. pyogenes bears a general resemblance to the changes occurring in tuberculosis and in actinomycosis."

B. pyogenes is deemed undoubtedly the most common suppurative organism affecting swine. Abscesses caused by it may develop in all parenchymatous visceral organs, the walls of the gastro-intestinal canal, the musculature, and the subcutis. It is also said to be quite as important in cattle as in swine.

The diastase in the saliva of the ox, C. C. PALMER (Vet. Alumni Quart. [Ohio State Univ.], 4 (1916), No. 2, pp. 44-52).—Previously noted from another source (E. S. R., 36, p. 82).

The diagnosis of infectious abortion of cattle (Bang's disease) with special reference to the intradermal abortin test.—I, Review of Bang's disease, J. Reichel and M. J. Harkins (Jour. Amer. Vet. Med. Assoc., 50 (1917), No. 7, pp. 847-862, figs. 4).—This is a general discussion of the subject with regard to history, symptoms, bacteriological examinations (microscopic and cultural), and biological tests (serological and diagnostic reagents), together with detailed tabulated data on the use of the "abortin" test as introduced by the British commission (E. S. R., 22, p. 584) and also tested by Meyer and Hardenbergh (E. S. R., 31, p. 380).

The abortin used was prepared by removing from six to eight strains of *Bacillus abortus*, which were grown in Blake bottles of neutral glycerin agar at 37° C. until their maximum growth was obtained, with sterile physiological salt solution, collecting as one mixture, heating to 60° for one hour, and centrifugalizing. The killed bacteria were then once more washed with physiological salt solution and the emulsion shaken up in a mechanical mixer with a definite amount of the saline and filtered through four thicknesses of sterile cheesecloth. The filtrate was so diluted that each cubic centimeter included approximately 5,000,000,000 bacteria, cultured for sterility and preserved with 0.5 per cent phenol. It was applied in the test in a manner similar to the intradermal tuberculin test as used by Haring and Bell (E. S. R., 30, p. 883).

It is indicated that the intradermal test is hardly destined to assist in establishing a diagnosis, as far as the individual animal is concerned, but as an aid in determining whether or not the infection actually exists in a herd it is a valuable test for the practicing veterinarian. "As much can be said for a positive reaction in the test as a positive reaction in any of the serological tests, and when the history of the herd is such as to arouse the suspicion that

Bang's disease may exist, then positive reaction with the intradermal abortin test in several animals would show that the suspicion is well founded, whereas uniformly negative results would tend to indicate that the infection was not present.

"Outside of clinical observations, including the history of the herd and deductions made of material aborted, the veterinarian must rely on the results of tests that include laboratory procedures, the results of which as a rule are very difficult to interpret. . . . When the results of the bacteriological or serological tests are available the results of the intradermal abortin test can be used as additional confirmation, and if circumstances prevail where bacteriological or serological tests can not be made then the intradermal abortin test can serve as an additional means or procedure open to the veterinarian in practice."

Formalin in the treatment of mastitis, J. N. Frost (Jour. Amer. Vet. Med. Assoc., 51 (1917), No. 1, pp. 85-88).—The author reports having obtained gratifying results from the administration of formalin by mouth in the treatment of infectious mastitis. In his experiments 25 cc. of formalin given to a cow undiluted in capsules twice daily for two weeks failed to produce ill effects in any way, either by loss of appetite, constipation, or emaciation. Fifty cc. was also given at one time without ill effect. Five cases of mastitis cured by this treatment are reported.

When one dram of formalin was given faint traces could be found in the milk in 24 hours. When 25 cc. was given three hours after water and seven hours after milking it was found in the milk two hours afterwards and continued to be present for 48 hours.

Eradication of the cattle tick in Argentina, A. AYERZA, F. SIVORI ET AL. (An. Soc. Rural Argentina, 50 (1916), No. 6, pp. 582-584).—A plan for the eradication of the cattle tick in Argentina, prepared by a commission appointed by the Minister of Agriculture, is presented.

Notes on a fatal parasitic infestation in a herd of cattle and goats in the Province of Ambos Camarines, W. H. BOYNTON and L. D. WHARTON (Philippine Agr. Rev. [English Ed.], 9 (1916), No. 4, pp. 348-353).—This\_paper reports upon the occurrence in the Province of Ambos Camarines of helminths in cattle and goats which had succumbed to their attack. The helminths dealt with are Bunostomum phlebotomum, Œsophagostomum columbianum, Œsophagostomum sp., Hæmonchus contortus, Trichuris ovis, Filaria labiato-papillosa, nematode species, and Paramphistomum sp.

Louping-ill, S. Stockman (Jour. Compar. Path. and Ther., 29 (1916), No. 3, pp. 244-264).—This article, which deals particularly with the possibility of the transmission of this disease by ticks, includes reports of experiments in which the tick theory was tested.

"The experimental evidence so far is against the view that louping-ill is a disease carried by ticks. There still remains to be tested by direct experiment, however, the possibility of ticks acquiring infection when sucking as larvæ, remaining noninfective in the nymphal stage, and developing infectivity when adults."

The author concludes that until the experiments now being carried out have been completed it will be unwise to conclude that louping-ill is not a tick-borne disease.

Roundworms of sheep, B. H. RANSOM (U. S. Dept. Agr. Rpts. 1916, pp. 127-130).—During 1915 nematode experiments were made at Vienna, Va., with approximately 100 ewes and lambs separated into four lots. The first lot was kept continuously on the same pasture from May to September. The second lot was kept on a double pasture from May to September, grazing alternately

two weeks in each of the two parts. The animals in the third lot were grazed separately and moved every week to fresh ground or ground not recently grazed, but were allowed together at noontime and night, when they were together in a barn with slat floors which was cleaned and disinfected at least once a week. The fourth lot was moved once a week from May to September to fresh pasture and was kept together most of the time, the ewes occasionally being separated from the lambs and grazed on infested pasture when the available fresh pasture was limited.

At least five lambs from each of the lots were killed and examined in September or later, but no material difference was observed in the degree of stomach worm infestation in the various lots. A great reduction in the number of stomach worms present occurred in all of the lots after November 1, as a rule only a comparatively few individual worms being found instead of the usual thousands found in the lambs or ewes examined earlier.

With reference to hookworms, nodular worms, lungworms, and tapeworms, there was no important difference between the first and second lots. The lambs of the third lot showed hookworms in only one case and then only two specimens. They had few and in some cases no nodular worms or worm nodules, no tapeworms, and no lungworms. The lambs in lot 4 also had comparatively few hookworms, nodular worms, and worm nodules, only one having lungworms and none tapeworms.

These experiments apparently indicate that the plan followed as to change of pastures can not be depended upon to control parasitic infestation in lambs, especially in the case of the stomach worm, although, on the other hand, it appeared that a change of pasture every week during the season from May 1 to September 1 kept down the infestation of lambs with hookworms, nodular worms, lungworms, and tapeworms to a very small amount. It thus appears that these parasites can be more easily controlled than the stomach worm by a system of pasture rotation. "The probable meaning of the presence of only a few stomach worms in sheep during the winter following a summer in which they were comparatively numerous in other sheep of the same flock is that the average length of life of the adult stomach worm is not more than a few weeks or months; in brief, that the stomach worm is essentially a short-lived parasite."

The influence of partial thyroidectomy in pigs, C. C. Palmer (Amer. Jour. Physiol., 42 (1917), No. 4, pp. 572-581, fig. 1).—The results of a study by the author at the Veterinary Research Laboratories of the Minnesota Experiment Station show that the extirpation of the main thyroid gland in young pigs does not induce cretinism, at least within a period of nearly one year. A slight retardation of growth was observed, but the operated pigs otherwise acted similarly to the controls except that they showed a marked lowered resistance to infection. A marked hypertrophy of the accessory thyroid tissue was observed on post-mortem examination of the thyroidectomized pigs.

It is indicated that "the main thyroid gland plays an important part in the normal body resistance to infection, and when this structure is removed the accessory thyroids can not completely compensate. In pigs a degree of hypothyroidism not sufficient to lead to marked changes in physical appearance of the animal lowers the resistance to infection to quite a degree, and impairs the functions of reproduction."

Fetal athyrosis.—A study of the iodin requirement of the pregnant sow, G. E. Smith, with the cooperation of H. Welch (Jour. Biol. Chem., 29 (1917), No. 2, pp. 215-225).—The authors, at the Montana Experiment Station, have studied the condition of the birth of hairless and otherwise defective pigs

which has been reported from western North Dakota and South Dakota, Washington, Minnesota, and western Canada.

The affected pigs when born are of full size and occasionally larger than normal. They are, however, strikingly weak and low in vitality, although born of apparently normal sows. Except for a few hairs on the nose and a few around the eyes, the skin is smooth, shiny, and bald. This hairless condition is, however, very variable. The skin, particularly around the shoulders, is thick and feels pulpy, but on incision no fluid escapes, although it appears edematous. The hoofs are thin-walled, short, brittle, and in an undeveloped condition. The thyroid is dark red and sometimes almost black, and histological examination shows a uniform hyperplasia and a distention of the blood vessels. Chemical examination of the thyroids showed the iodin content to be extremely low in comparison with normal glands. In general, the iodin content of a diseased gland was found to vary inversely with the hairlessness of the animal. The glands of the affected pigs also showed a large accumulation of iron. The data are presented in tabular form.

Pregnant sows in the affected districts which were fed potassium iodid and desiccated sheep thyroid in the last four or five weeks before farrowing gave birth to strong and vigorous young, while the young of the control animals were weak, dull, and lacked vitality. The significance of the iodin feeding is discussed.

It is concluded in general that an iodin deficiency during the gestation period causes a lack of function and hyperplasia of the fetal thyroid, resulting in an arrested development of the fetus. "If more iodin were fed to the pregnant animals in large sections of this continent, especially during the winter months, the young that they produce would be more healthy and more vigorous and the large number of weak and defective young animals that are produced annually would be greatly reduced. Fetal athyrosis presents strong evidence that there is a direct relation between the physiologically active constituents of the thyroid and growth of the epidermal appendages. An abundant secretion of the fetal thyroid, during the later stages of the intrauterine life, is essential for the normal development of the fetus."

The spirochetes of the digestive tract of swine and their relation to hog cholera, P. Bekensky (Rec. Méd. Vét., 92 (1916), No. 19, pp. 545-552).—The author has examined the intestinal tract of 100 hogs at an abattoir and found spirochetes in 58 per cent of the cases. The spirochetes were found not only in animals affected with hog cholera but also in animals affected with other diseases. It is indicated that in hog cholera these organisms might provoke a secondary infection (as is often the case in infectious diseases), but that the disease is fundamentally due to the invisible microorganism. The data obtained are discussed in some detail.

Swine fever, J. O. Powley (Vet. Rec., 29 (1917), No. 1497, pp. 383-390).— This is a general discussion of the subject under the topics of history, etiology, semeiology, post-mortem appearances, diagnosis, methods of infection, treatment, efficacy of serum, and a brief account of the preparation of serum.

A granulomatous affection of the horse—habronemic granulomata (cutaneous habronemiasis of Railliet), L. B. Bull (Jour. Compar. Path. and Ther., 29 (1916), No. 3, pp. 187-199, figs. 5).—"The granulomatous condition found on the penis and sheath, and infrequently in other situations, has the same etiology as summer sores. The parasite associated with the condition is a larval nematode of the genus Habronema. This parasite is accidental, and probably can not maintain its life for longer than four weeks. The parasite is almost certainly carried by a biting fly, and is accidentally inoculated during the feeding operations of the fly. The tissue reaction following the introduction

of the parasite leads to a tumor presenting a characteristic macroscopic and microscopic appearance. The affection known as swamp cancer in the Northern Territory of Australia is almost certainly a variation of the same condition.

"Prophylaxis should be in the direction of (1) ridding horses of the adult forms of the genus Habronema which are located in the stomach, and (2) in the destruction of feces which bear the embryos and which act as a breeding ground for flies. Complete excision of the lesion before it has become inoperable is the only treatment to be advised."

Sclerostome parasites of the horse in England.—II, New species of the genus Cylichnostomum, C. L. Boulenger (*Parasitology*, 9 (1917), No. 2, pp. 203-212, figs. 5).—This second part of the paper previously noted (E. S. R., 36, p. 280) consists of descriptions of three new species of the genus Cylichnostomum.

Parasitic occurrence of Eimeria stiedæ in the liver of the dog, A. Guillebeau (Schweiz. Arch. Tierheilk., 58 (1916), No. 11, pp. 596-602, figs. 6; abs. in Rec. Méd. Vét., 93 (1917), No. 1-2, pp. 71-73; Trop. Vet. Bul., 5 (1917), No. 1, pp. 5, 6).—The author describes two cases of the occurrence of E. stiedæ in the liver of dogs, 10 and 13 years old, respectively, in which great enlargement of the abdominal cavity was the most marked symptom during life. Coccidiosis of the liver, although common in rabbits, is said to be very rarely found in the pig or dog.

Chick troubles, W. C. Thompson (New Jersey Stas. Hints to Poultrymen, 5 (1917), No. 7, pp. 4).—This circular discusses a few of the more common chick troubles, especially those that usually appear when chicks are brooded in large colonies.

Apparent recovery of a hen infected with bacillary white diarrhea as determined by the macroscopic agglutination test, G. D. Horton (Jour. Bact., 1 (1916), No. 6, pp. 625, 626).—The author reports upon the recovery of a Bantam hen, indicating the possibility of recovery or the throwing off of ovarian infection.

The part played by the goblet cells in protozoan infections of the intestinal tract, P. B. Hadley (Jour. Med. Research, 36 (1917), No. 1, pp. 79-86, pl. 1).—"The present paper presents observations which demonstrate that, in the case of the flagellate protozoan, Trichomonas, the cause of an acute malady of several species of birds, notably the turkey (blackhead), the avenue of invasion of the subepithelial tissues is the goblet or chalice (gland) cells located in the fundus of the crypts of Lieberkühn. It is suggested that the passage of the parasites through these cells is not inadvertent, but due to a natural invasive power present in the motile flagellate trophozoite which accomplishes the infection of the deeper tissues."

Eimeria avium: A morphological study, P. B. Hadley and Elizabeth E. Amison (Arch. Protistenk., 23 (1911), No. 1-2, pp. 7-50, pls. 2).—Following an introduction and historical résumé the authors discuss the material, methods, and technique and the life cycle of the coccidium and the infectious process; and give a detailed description of the several stages of the coccidium, namely, the mature cyst, sporoblasts, sporozoites, schizonts, merozoites, macrogametes, microgametocytes, and microgametes.

A list of 37 references to the literature is included.

Coccidia in subepithelial infections of the intestines of birds, P. B. HAN LEY (Jour. Bact., 2 (1917), No. 1, pp. 73-78).—This is a brief report of studies of coccidia now in progress, in continuation of investigations above noted, in which the author considers in a preliminary way the bearing of certain of the observations upon the problem as discussed by Smith 18. S. R., 35, p. 684).

"Although the full significance of the presence of merozoites and of other stages of *Eimeria avium* in subepithelial regions of the intestines can not yet be grasped, their frequency of occurrence there and their freedom from all appearances of degenerative changes lead us to assume that this phenomenon marks an ordinary phase of the normal infective process; and that so far as the coccidia are concerned, we must, as the writer pointed out some years ago, abandon the view that they are exclusive parasites of epithelial cells in the sense that they must occupy epithelial cells to complete their normal development."

Another case of the occurrence of the giant nematode, Dioctophyme renale, in the abdominal cavity, and data bearing upon the theory of entry via the genito-urinary tract, W. A. RILEY (Cornell Vet., 7 (1917), No. 1, pp. 43-45).—The data here presented supplement the account previously noted (E. S. R., 36, p. 86).

### RURAL ENGINEERING.

Proceedings of the second, third, and fourth annual meetings of the Washington Irrigation Institution, December, 1914, January, 1916, and November, 1916 (*Proc. Wash. Irrig. Inst.*, 2 (1914), pp. 163, fig. 1; 3 (1916), pp. 214, fig. 1; 4 (1916), pp. 141, figs. 3).—These proceedings contain, respectively, the following special articles bearing on irrigation engineering:

Second meeting.—Experience with Canal Lining, by E. M. Chandler; Canal Lining Experience, by J. G. Heinz; Plant Growth in Canals, by F. C. Lee; Methods of Water Delivery, Rotation, and Size of Head, by M. Chase; Operation of the State Drainage Law, by W. B. Bridgman and J. O. Greenway; The Use of Electric Power in Pumping Water for Irrigation, by H. D. Hanford; Discussion of Drainage and Reclamation of Alkali Land, by H. E. Nicolai; Hydrated Lime in Irrigation Work, by C. D. Smith; Economy, Durability, and Efficiency of Water Distribution Systems, by A. B. Fosseen; Vitrified Clay Pipe for Irrigation and Drainage, by W. M. Watt; Irrigation District Laws, by C. B. Graves; The State College and Irrigation, by E. A. Bryan; The Farmer's Part in Irrigation Development, by S. Fortier; The Use of Metallic Flumes and Pipes in Irrigation Development, by G. L. Hess; and Duty of Water, by S. O. Jayne. Articles on Plaster Concrete Lining for Canals and Laterals, by C. Casteel; and Experience with Wood Stave, Concrete, and Steel Pipe, by E. M. Chandler, are appended.

Third meeting.—Irrigation Conditions, by E. F. Benson; Maintenance and Construction of Metal Flumes, by W. B. Armstrong; Uses of Concrete in Irrigation Development, by C. N. Reitze; Irrigation Pumping by Means of Electric Pumping, by G. Longmuir; Irrigation Pumping, Other Methods, by S. B. Hill; Wood Pipe, Its Uses and Limitations, by T. A. Noble; and Conflicting Interests in Water Legislation, by W. F. Allison. Descriptions of irrigation projects in the State are included.

Fourth meeting.—Method and Time of Applying Water, by O. L. Waller; Wood and Thin Metal Pipe, by T. A. Noble; Light Iron Pipes, by C. Casteel; The Value of Irrigation to the State, by M. Chase; Metal Flumes, by W. B. Armstrong; Metal Flumes as Canal Lining, by E. M. Chandler; The Agricultural Duty of Water, by J. C. Wheelon; Drainage, by G. Severance; Wooden Flumes, by W. F. Allison; Oil-Burning Engines, by J. B. Frem; and Cement Lining of Canals, by C. Casteel.

Flow through submerged rectangular orifices with modified contractions, V. M. Cone (U. S. Dept. Agr., Jour. Agr. Research, 9 (1917), No. 4, pp. 97-114, flgs. 13).—Experiments conducted at the Colorado Experiment Station in

cooperation with the Office of Public Roads and Rural Engineering of the U.S. Department of Agriculture are reported, which consisted of 317 observations, with 60 different combinations of sizes of orifices, sharp and thick edges, with and without gate guides, with and without small bottom contraction, with different depths of water in the channel of approach, and with different end contractions in the channel of approach and recession.

The results of the experiments are summarized and a consolidation of the expressions for the exponent and coefficient values of the head, h, "gives the general formula for the discharge through submerged rectangular orifices placed according to the conditions which have been taken as the standard:

$$\mathbf{Q} = \left( \frac{(0.02d + 0.99)}{(4.8 + 0.1d)a} \right)_{h} \left( 0.495d + 0.06d - \frac{7.26a}{\mathbf{A}} \right)$$

In which Q=the discharge in second-feet; d=depths of orifice in feet; a=area of orifice in square feet; A=area of cross section of water in channel of approach in square feet; and h=the difference in feet between the water levels upstream and downstream from the orifice."

The agreement of the discharge formula with the experimental data is shown to be within a mean of approximately 0.5 per cent, with a few individual exceptions, which are more than 1 per cent off.

The standard conditions are taken as follows:

"The total length of the orifice box is 16 ft., 10 ft, of which forms the channel of approach. Wings set at an angle of 90° are attached to the sides of the upstream end of the orifice box. The floor of the box is level throughout and at the same elevation as the bottom of the canal. The box should be set in the center line of the canal, so as to allow the water to enter the box in straight lines. The sides are parallel and are placed apart a distance equal to the length of the orifice plus 2 ft.

"Orifices of all sizes have end-contraction distances of 1 ft. The orifice must have sharp sides and top, and no bottom contraction. . . . The orifice must be placed with its greatest dimension horizontal. If it is desirable to use an orifice with bottom contraction, or with wood sides and top, or with gate guides and gate, the discharge tables may be corrected in accordance with the data given. . . .

"The elevations of the water levels in the channels of approach and recession should be taken in separate stilling boxes, one connection being 5 ft. upstream and the other 1.5 ft. downstream from the plane of the orifice. The connections should be through the side of the orifice box about 0.5 ft. above the floor line."

A few supplemental experiments are also reported.

The Venturi flume, V. M. CONE (U. S. Dept. Agr., Jour. Agr., Research, 9 (1917), No. 4, pp. 115-129, pls. 4, figs. 8).—"The purpose of this article is to present the fundamental plans and results of preliminary experiments on a new type of device, called the 'Venturi flume,' for measuring water in open channels."

The flume "consists essentially of a flume with a converging and a diverging section and short 'throat' section between them. The floor, which is level, is placed at the elevation of the bottom of the channel in which it is set. . . .

"The action of this device depends upon an adaptation or extension of Venturi's principle to the flow of a liquid in an open channel. As water passes through the flume there is a slight surface slope in the converging section, a rather sudden depression in the 'throat' section, and a rise in the diverging section. The actual loss of head is small. The determination of the flow

depends upon the velocity and wetted cross-sectional area at two points in the flume, and two gage readings, therefore, are necessary."

From the experimental data the formula for discharge through the V-notch Venturi flume is as follows:

$$\mathbf{Q} \! = \! 6.68 \mathbf{H_{b}^2} [(\mathbf{H_d} \! - \! 0.14 \mathbf{H_a} \! + \! 0.02)^2 \! + \! 0.01 \mathbf{H_a} \! + \! 0.56] \sqrt{1 \! - \! \frac{\mathbf{H_d}}{\mathbf{H_{b}^4}}} \! \\ - \frac{\mathbf{H_d}}{(2\frac{2}{3} \! + \! \mathbf{H_a})^2 \mathbf{H_a^2}}$$

In this formula Q=the discharge in second-feet;  $H_a$ =the head at the gage in the upstream section;  $H_b$ =the head at the throat section; and  $H_d$ = $H_a$ - $H_b$ .

"The discharge through the Venturi flume with trapezoidal cross section, having side slopes of 1:1 in a plane normal to the axis of the flume and with a bottom throat width of 6 in., is represented by the following equation, which was derived in a manner similar to that given for the V-notch Venturi flume:

$$Q = \begin{bmatrix} \frac{[(H_d - 0.09H_a - 0.005)^2 + 0.001H_a + 0.274]}{0.30} \end{bmatrix} \quad (\frac{1}{2} + H_b)H_b$$

$$\sqrt{1 - \frac{\frac{2gH_d}{(\frac{1}{2} + H_b)^2H_b^2}}{\frac{1}{2^4} + H_a)H_a^2}}$$

"The Venturi flume is not an exact measuring device, but it is thought to be sufficiently accurate to meet usual practical needs, especially such as are encountered in irrigation practice in the West. Although experiments have been made only on the smaller sizes of Venturi flumes, it seems reasonable to expect that structures built according to the general plans will be applicable to the measurement of streams of considerable size with an accuracy compatible with field requirements. The Venturi flume seems to fulfill the conditions of being free of trouble from sand, silt, or floating trash; requires little loss of head for making the measurement; is a structure that is simple to build, easy to operate, and has a comparatively low cost; and is free from error in measurement due to aquatic growth or other changes in the channel, provided the floor of the flume is not below the grade of the channel."

Investigations of irrigation pumping plants, H. E. Murdock (Montana Sta. Bul. 115 (1917), pp. 125-148, figs. 6).—Field and laboratory tests of pumping outfits, consisting of various combinations of engines and pumps for different heads, are reported. The results of the laboratory tests are summarized in the following table:

# Summary of results of laboratory tests.

Kind of engine.	Kind of pump.	Engine, rated horse- power.	Engine speed (revo- lutions per min- ute).	Pump speed (revo- lutions per min- ute).	Dis- charge of pump per second.	Lift.	Fuel per foot acre- foot.	Lubri- cating oilsper foot acre- foot.

Growth of moss in irrigation canals, Salt River Project, A. J. Haltom (Reclam. Rec. [U. S.], 8 (1917), No. 4, pp. 191, 192).—Studies of the growths of moss which obstruct the flow in the wide, shallow, low-velocity canals of the project led to the following conclusions:

"Moss does not grow in canals of high velocity. Neither does it flourish in canals that have uniform grades, but canals of uneven grades which contain low spots are very favorable for healthy growth. Moss does not grow in the absence of sunlight. It does not grow in canals with water depth of more than 5 ft. It flourishes best in canals with a silt bottom because the silt furnishes an excellent medium for root development. It obtains its healthiest growth in clear water. Muddy water retards but does not completely stop its growth."

The best results in experiments on control "were obtained with an Acme harrow. This machine was used with such satisfactory results that it is highly recommended for the removal of moss under conditions similar to those on this project."

Control of moss, weeds, and willows on the Minidoka Project, B. DIBBLE and T. W. Parry (Reclam. Rec. [U. S.], 8 (1917), No. 4, pp. 192, 193, fig. 1).— In experiments on the control of moss and weeds on the project during June "the only method which was found successful in clearing the moss from the larger canals was by cutting with the Ziemsen submarine saw.

"This saw consists of a flexible band of steel with hooked teeth on both edges. It can be obtained in any length, and the weights to hold it to the bottom are adjusted to fit the canal. It is operated at an angle of about 30° with the cross section of the canal, the crew always working upstream. The rate of progress is from 6 to 12 in. at each double stroke and from 0.25 to 1 mile per day can be cut with each saw. The long streamers of moss when cut rise to the surface and float down to the next bridge or check, where they are thrown out by men with pitchforks. . . .

"Where it can be done the cheapest and most effective method of cleaning the canal is to shut the water out entirely and let the ditch dry in the sun. Five to seven days' exposure is necessary ordinarily to kill the moss. This method kills the growth, but does not destroy the bulb. . . .

"During the 1916 season 260 miles of cleaning were done. The total cost of this work was \$4,200, making the cost per mile a fraction over \$16. The average cost per mile of the different methods is about as follows: Sawing \$22, chaining late in the season \$8, cutting with scythes in laterals \$11, and spring-tooth harrow in laterals \$9....

"Willows are cut by men with grubbing hoes and brush scythes. Men equipped with grubbing hoes go ahead for cutting out larger willows, and men with scythes follow and cut the remainder."

Drainage (Minnesota Sta., Rpt. Crookston Substa., 1910-1916, pp. 20-27, ftgs. 3).—This is a brief report on a seven years' test of a tile drainage system at the Northwest Substation at Crookston, Minn. The soil is a dark, sticky clay loam with a heavy compact bluish gray clay subsoil.

"Tile drainage is limited in operation to the period after the frost is out above them. This makes shallow surface ditches necessary for early spring drainage. Observations have emphasized the necessity of supplementing tile drains with surface ditches during the entire growing season in order to secure the best results. . . . The drainage system has been found to be of the greatest service. The two detailed inspections which have been made, in 1912 and 1916, showed the tile in as good condition as in other localities."

By-products of land clearing (Minnesota Sta., Rpt. Duluth Substa., 1916, pp. 9, 10).—The receipts per acre for lumber, cordwood, and fence posts were found to be \$62.08, with a total cost for clearing up to the stumping stage of \$57.39 per acre.

The soil saving dam, W. H. BAKER (Univ. Missouri Agr. Ext. Serv. Circ. 14 (1917), pp. 4, figs. 3).—This circular describes and illustrates the construction of dams the purpose of which is to hasten the filling up of washed ditches on farms by preventing the sudden run-off of storm water.

A comparative bacteriological study of the water supply of the city and county of Denver, Colo., W. G. Sackett (Colorado Sta. Bul. 225 (1917), pp. 3-14, pls. 4, flgs. 2).—This bulletin describes the water supply system of the city and county of Denver, Colo., and the methods of purification in use and reports comparative bacteriological tests of samples of the purified water made by four different experimenters, of which the author reported for the Colorado Station.

In these tests the results from the four sources were very uniform. Attention is called "to the excellent and safe condition of the filtered and treated waters as shown by the low gelatin and agar counts and by the total absence of Bacillus coli from the main supply, complying in all respects with the standard adopted by the Public Health Service of the U. S. Treasury Department."

Data on the prevalence of typhoid in the city and county of Denver and the text of the ordinance protecting the watershed are also given.

The activated sludge process of sewage purification, E. Arden (Jour. Soc. Chem. Indus., 36 (1917). No. 2, pp. 65-68; Surveyor, 51 (1917), No. 1314, pp. 298-300).—Further studies on the activated sludge process (E. S. R., 34, p. 888), including experiments on the effect of trade effluents on the process, are reported.

It was found "that, contrary to the opinion formed as the result of earlier experiments when working with a strong trade sewage, the maintenance of the activity of the sludge is not dependent on the stage to which nitrification is carried. When dealing with a sewage free from inhibitory trade effluents no appreciable loss of efficiency need be anticipated in this country [England] during the winter months. While the problem of disposal of the sludge remains to be fully developed, it would certainly appear from known data that the cost of dewatering and drying will be more than repaid by the value of the resultant dried sludge."

Sewage disposal for village and rural homes, C. S. Nichols (*lowa Engin. Expt. Sta. Bul. 41* (1916), pp. 29, figs. 10, pls. 3).—It is the purpose of this bulletin to correct dangerous misconceptions recently published about septic tanks, to point out the general principles covering the proper disposal of household

wastes, and to illustrate some practical designs for sewage-disposal plants for construction by the average householder which are the results of experiments at the engineering experiment station.

It is pointed out that "septic tanks are only water-tight cesspools provided with an overflow. . . . A septic tank is only a receiving tank for the sewage in which the solid material is settled out and allowed to remain for 'septic' (i. e., bacterial) action. Experience has shown that certain provisions as to size, shape, and structural details will facilitate the proper operation of such a tank, although septic action will take place in any receptacle which will retain sufficient liquid to cover the solid material and exclude light and air. . . . The liquid escaping from such tanks, whether through a tile overflow from a tight tank or through the porous soil or rock seams of a 'leaching' (not water-tight) cesspool, is extremely foul, and is dangerous to life and health."

The two fundamental principles of sewage disposal are said to embody two distinct, supplementary, and equally necessary treatments, as follows: "(1) Septic action, in a properly arranged, water-tight, covered, masonry tank for removing, retaining, and decomposing the solid material contained in the sewage; and (2) filtration and consequent oxidation and nitrification, by means of a properly arranged and maintained area of porous material through which the effluent from the tank is filtered and subjected to bacterial action.

"In general, it may be said that only approximately one-third of the necessary purification takes place in the tank. The degree of further purification will depend upon the type of filter chosen, its construction, care, and operation."

As a current breaker, it was found in the experiments that an ordinary box 12 by 12 in., open at the top, bolted to the end of the wall of the tank, and receiving directly the downward discharge of the inlet pipe through an elbow on the end, is effective. An upward sand filter at the outlet was found to minimize the passing on of sediment due to disturbance to the filter bed.

With reference to filters, "experimentation has shown that a bed of ½-in. pebbles, with ample provision for its aeration and the even distribution of sewage in small quantities over its surface will do good work and discharge an effluent comparatively free from offensive materials. With such beds it is necessary that very special precautions be exercised to insure thorough aeration so that the purifying agencies may have a constant supply of oxygen." Intermittent sand filters are also discussed.

"The size of the dosing chamber is made such that the quantity of sewage discharged will flood the bed to a depth of only about ½ in., this being repeated from two to four times during 24 hours."

Diagrammatic illustrations of three plants designed at the station are presented.

Designs for privies, R. Messer (Amer. Jour. Pub. Health, 7 (1917), No. 2, pp. 190-196, figs. 5).—The author briefly describes and illustrates several well-known types of so-called sanitary privies and points out the advantages and disadvantages of each. It is believed "that some modification of the L. R. S. wet closet is the most satisfactory that has yet been suggested, and, furthermore, the additional expense of building is more than offset by permanency and small cost of maintenance. That the problem is far from being satisfactorily solved is clearly evident."

Hydroelectric power.—I, Hydraulic development and equipment; II, Electrical equipment and transmission, L. Lyndon (New York: McGraw-Hill Book Co., 1916, vols. 1, pp. VII+499, pl. 1, figs. 234; 2, pp. VII+360, figs. 194).—This work is in two volumes. It is the author's purpose "to produce

a work for the guidance of engineers in the practical design of hydroelectric plants which would have the characteristics of accuracy, clearness, and completeness. Scientific discussions of various hypotheses and theories have been omitted except in cases where their incorporation in the text has been essential to the understanding of the subjects treated. . . . A number of new and original formulas appear, for the first time, here. Among these may be mentioned the exact formulas for solid dams and for the magnitude and location of the resultants of forces acting on dams."

Volume 1 contains the following chapters: General conditions, flow in streams. weirs and orifices, power variation and storage, artificial waterways, pipe lines and penstocks, dams, movable crests for dams, headworks, water wheels, speed regulation of water wheels and abnormal penstock pressures, and a set of mathematical tables. Volume 2 contains the following chapters: Alternating current generators, transformers, switchboards, cranes, design and testing of power stations, fires and cables, insulators, pole and tower lines, electric circuits, calculation of transmission lines, deflection and mechanical stresses in transmission lines, line protection and accessories, and substations.

Methods and cost of screening and washing gravel for country road construction, A. A. McKay (Engin. and Contract., 47 (1917), No. 14, pp. 318, 319).—This is a description of methods of obtaining gravel of extra good quality from low-grade gravel in Calhoun County, Mich.

Tests on corrugated metal culverts (Technol. Expt. Sta. [Univ. Me.] Bul. 2 (1916), No. 1, pp. 15, flys. 2).—Tests of the physical characteristics, crushing strengths, amount of zinc coating, and acid tests of 13 galvanized corrugated metal pipes are reported, the results being summarized in the following table:

Tests of corrugated metal pipes.

Туре.	Weight per foot.	Gage.	Inside diame- ter.	Character of as- sembly.	Crossing load per linear foot.	Zinc per square foot.	Acid test.

· Very scaly.

Public road mileage and revenues in the Central, Mountain, and Pacific States, 1914 (U. S. Dept. Agr. Bul. 389 (1917), pp. 56+LXXV, fig. 1).—This report, prepared jointly by the Division of Road Economics of the Office of Public Roads and Rural Engineering and State collaborators, is a compilation showing mileage of improved and unimproved roads, sources and amounts of road revenues, and bonds issued and outstanding in the States of Arizona,

California, Colorado, Idaho, Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Montana, Nebraska, Nevada, New Mexico, North Dakota, Ohio, Oregon, South Dakota, Utah, Washington, Wisconsin, and Wyoming. A description is also given of the systems of road administration, fiscal management, and other factors affecting road improvement in each State.

Public road mileage and revenues in the United States, 1914: A summary (U. S. Dept. Agr. Bul. 390 (1917), pp. 11, fig. 1).—This is a summary, prepared jointly by the Office of Public Roads and Rural Engineering and State collaborators and based upon Bulletins 386, 387, 388, and 389, showing for each State the total and surfaced mileage of public roads at the close of 1914, revenues for roads and bridges in 1914, State and local road and bridge bonds outstanding January 1, 1915, and other related data.

Maine State Highway Commission ([Augusta, Me.: State, 1915], pp. 64+30).—This pamphlet gives the texts of the laws of Maine relating to the laying out, construction, and maintenance of highways under the supervision of the State highway commission, including the law of the road. A section is appended on an act to establish a State highway commission and to provide for an issue of State highway bonds.

Building a farm poultry house in northwestern Minnesota, C. E. Brown (Minnesota Sta., Rpt. Crookston Substa., 1910-1916, pp. 97-102, figs. 6).—This is a brief outline of the essentials of poultry-house construction for northern latitudes, including plans showing certain structural details.

Poultry management (*Minnesota Sta. Rpt. 1916*, pp. 78, 79).—A study of the comparative values of glass and muslin screening in poultry-house construction showed that the average temperature was lower for the muslin front than for the glass front at 7 a. m., 1 p. m., and 7 p. m. Observations were made from January 12 to March 31, inclusive.

## RURAL ECONOMICS.

Food supply of the United States, D. F. Houston (U. S. Dept. Agr. Rpts. 1916, pp. 10-13).—It is pointed out that within the period 1889-1915, inclusive, the population of the Nation has increased 26,000,000, or 33 per cent, but that, notwithstanding this very rapid increase in population, the per capita production of fish, cereals, potatoes, and vegetables has remained approximately the same, or has increased slightly. The per capita production of meat and dairy products, which constituted 37 per cent of the average diet, has not kept pace with the increase in population. The activities of the Department have taken two important directions to increase the supply, that is, by checking and eliminating disease and parasites, and by increasing and improving stock raising by extending the industry where conditions are favorable and by pointing out the way to better breeding and feeding. With all the agencies now available for improving agriculture, there is said to be reason for optimism as to the ability of the Nation, not only to supply itself with food, but increasingly to meet the needs of the world.

Some fundamental considerations affecting the food supply of the United States, T. F. Hunt (California Sta. Circ. 163 (1917), pp. 3-13, fig. 1).—On this memorandum prepared for the committee on resources and food supply of the State Council of Defense, the author points out that the Nation can not be starved as long as there is an abundance of corn and cotton. It is not deemed advisable to attempt to control food production by legal or military means, nor is admonition necessary to the farmer to grow materials so long as he understands which are likely, in the long run, to bring him the best returns for his

labor. Attention is called to the possible need of financing the farmer and conserving the labor supply.

Mobilization for food production, E. Davenport (Urbana: Univ. Ill., 1917, pp. 4).—The author outlines a scheme to provide farm labor to increase the food supply through the enlistment of certain groups of men and boys for food production and their mobilization at training camp farms. He maintains that limiting the food of the people is wholly unnecessary if reasonable attention is given to the business of production and the present farm labor supply is adequately increased.

"Universal military service" for farmers, E. H. Jenkins (Connecticut Sta. Bul. Inform. 7 (1917), pp. 4).—The author maintains that the place for the farmer who has tillable land and expert knowledge and machinery to make it produce food is not in the training camp but in the field. He considers it better to fit and plant all of the land which it seems possible to handle, with the present expectation of summer help, at a risk of loss of part of the crop, rather than through fear to plant only that which there is a certainty to be harvested.

The redistribution of the labor now employed in producing war supplies, H. H. Lund (Amer. Econ. Rev., 7 (1917), No. 1, Sup., pp. 238-250).—The author describes the methods used and results obtained by the Forward-to-the-Land League in placing city men on farms.

The land problem and rural welfare, P. L. Vogt (Amer. Econ. Rev., 7 (1917), No. 1, Sup., pp. 91-101).—"The most hopeful solution appears to be the control of tenantry through the exercise of the taxing power. If the tax were so adjusted as to give a strong inducement to the prospective absentee landlord to dispose of his land to the prospective tenant, much of the speculative holding of land would be quickly eliminated and prices of land to prospective purchasers would much more nearly equal their productive value. The inducement to transfer investment from land to other forms of property would work no great hardship to the owner, because under the rural credit law land mortgage bonds would be available as well as other types of securities the absentee ownership of which does not bring such serious difficulties in business management as does the absentee ownership of land."

Two dimensions of productivity, H. C. Taylor (Amer. Econ. Rev., 7 (1917), No. 1, Sup., pp. 49-57).—The author discusses the significance of capacity and efficiency as they relate to productivity, and the problem of land ownership on the part of the farmer. He illustrates his discussions by making comparisons of the results obtained by a study of 51 farms in Barron County, Wis., and the efficiency and capacity of a number of cows where detailed records have been kept.

Agriculture and the farming business, O. H. Benson and G. H. Betts (Indianapolis: The Bobbs-Merrill Co., 1917, pp. [16]+778, figs. 263).—This book attempts to bring together in one simple, nontechnical volume, the practical scientific information related directly to the every day problem of the farm and home. Among the topics studied are the organization of farm business, methods of growing and harvesting crops, types of soil, live stock, the farm home and its management, farm machinery, and education for farm life.

Profits in farming on irrigated areas in the Gallatin Valley, Mont., E. L. Currier (Montana Sta. Bul. 111 (1916), pp. 52, fig. 2).—This bulletin gives the results of a farm-management survey made during the summer of 1914.

It was found that the average farm labor income on the farms studied was \$555. As the amount of capital increased, the labor income increased correspondingly. Farms which had a large percentage of their capital tied up in

real estate did not do so well as those that reserved an amount sufficient to adequately equip and operate their farms.

Farmers whose land was valued at \$100 an acre made better labor income than those with either higher or lower valuations. Farmers who sold a large percentage of their marketable crops had a better labor income than those who reserved a considerable portion for feed and seed, and farmers receiving a little less than one-third of their receipts from stock have a much better labor income than those who received either more or less from that source. The most favorable crop and stock relation seems to be attained on farms that have stock enough to utilize all cheap feeds and waste products but not so much as to require any considerable proportion of their feed to consist of products that have a high market value.

Tenants in this region receive a somewhat better labor income than do farm owners. The tenants are running a larger business and utilizing their land to better advantage than are those farmers that own their land. Tenants could improve their condditions by securing more and better live stock and owners could improve theirs by increasing the size of their business and using their land to fuller capacity.

The Federal Farm Loan Act, C. W. Thompson (Amer. Econ. Rev., 7 (1917), No. 1, Sup., pp. 115-131).—This paper discusses briefly the causes and steps leading up to the enactment of the Federal Farm Loan Act of 1916, the apparent intent of Congress in providing for two distinct farm mortgage bonding systems, the provisions for safeguarding the proper granting of farm mortgage credit, the means adopted for a form of security that will find ready access to the investment market, and the more important benefits that may be reasonably expected as a result of this system.

Report on the working of the cooperative societies in Bengal for the year 1915-16, J. M. MITRA (Rpt. Work Coop. Socs. Bengal, 1915-16, pp. 9+ 16+XIX).—This report continues the data previously noted (E. S. R., 36, p. 593), by adding data for a later year.

Agriculture in Oxfordshire, J. Orr (Oxford, England: The Clarendon Press, 1916, pp. XII+239, pls. 29, figs. 11).—The author describes the types of farming carried on in the different regions in Oxfordshire, and discusses the administration of the land, the management of farm labor, soils, crops, and live stock. The book contains a chapter on soils by C. G. T. Morison.

Crop condition and harvest field needs (Nebr. Dept. Labor Bul. 33 (1916), pp. 28, fig. 1).—This report contains data for the various counties in Nebraska, showing the acreage, average yield, total production of important crops, and demand for extra labor and wages during the previous year.

[Agricultural statistics of British Guiana], J. B. Harrison (Rpt. Dept. Sci. and Agr. Brit. Guiana, 1915, Apr.-Dec., pp. 22-24).—This report continues the data previously noted (E. S. R., 35, p. 795), adding statistics for a later year.

Return of prices of crops, live stock, and other Irish agricultural products (Dept. Agr. and Tech. Instr. Ireland, Agr. Statis. 1915, pp. 38, pls. 16, figs. 1).—This report adds to that previously noted (E. S. R., 33, p. 894) data for 1915.

Agricultural statistics of Finland for 1910 (Finland Off. Statis., III, No. 9, pt. 1 (1916), pp. VI+327).—This report contains data showing by minor subdivisions the area cultivated and not cultivated, the area devoted to different agricultural purposes and to individual crops and pastures, the number of farms by sizes and tenure, and the distribution of land among different agricultural uses on farms by sizes, together with data relating to agricultural machinery.

Prices of cattle and meat in Russia, A. ÎA. Korenblit (Kharkov. Obshch. Selsk. Khoz., Oblast. Kom. Peresmotru Russ.-Germ. Torg, Dogov., No. 8 (1915), pp. 84).—This report gives the monthly and yearly prices for 1903-1912 at Moscow and Petrograd for various classes of meat and cattle.

Live stock statistics [of Egypt, Spain, Morocco and Tunis] (Internat. Inst. Agr. Rome, Internat. Crop Rpt. and Agr. Statis., 8 (1917), No. 3, pp. 183-185).—These pages give the number of live stock, by classes, for 1916, with comparative data for earlier years.

## AGRICULTURAL EDUCATION.

State higher educational institutions of Iowa (U. S. Bur. Ed. Bul. 19 (1916), pp. 223, figs. 45).—This is a report of a survey of the State higher educational institutions of Iowa, made under the direction of the U. S. Commissioner of Education for the Iowa State Board of Education. Among the findings of the survey committee summarized in recommendations are the following:

The adoption of the principle of "major and service lines of work" at the three State institutions; the creation of an annual conference consisting of members of faculties of the institutions and the State board of education, to adjust questions of overlapping not automatically determined by the establishment of major lines for each institution; the readjustment of the work in engineering at the State University of Iowa and the Iowa State College of Acriculture and Mechanic Arts, through a vertical division of work, assigning some branches of engineering to one institution and some to the other; the encouragement of the development of graduate work at the State university and agricultural college along the major lines of the institutions; the exercise of greater care by the graduate division of the agricultural college in admitting students from other institutions to graduate standing; the creation of a standing committee on graduate work to consist of members of the State board of education and of the institutions giving graduate work, the latter to be elected by the graduate faculties; the strict enforcement by the State board of education of the principle that departments of liberal arts and sciences at the agricultural college shall be simply service departments, especially the revision of the work offered in the departments of economic science, geology, physics, and mathematics, to conform to this principle; the abandonment of courses in chemistry at the agricultural college which neither contribute to the major lines of that institution nor reinforce the work of the experiment stations; the revision of the requirements for the degree of bachelor of science in the division of industrial science to render it impossible to secure the degree except on completion of industrial and professional courses (in contradistinction to liberal arts courses) equal in amount to those required in technical curricula; the strict application of the principle of the major lines of work to the development of the extension enterprises of the three State institutions; the establishment of a conference on extension work, composed of members of the board of education and extension officers of the three institutions, to discuss projects; the imposition of no external limitations upon facilities offered at the three institutions for giving work for the training of teachers in home economics, agriculture, and manual training until the present force of teachers in the State schools is equipped to meet the obligations imposed by the State law; but thereafter the delimitation of work in psychology and education at the agricultural college to the amount requisite to meet the requirements of the first-class State certificate; the development at the university of home economics as a service department, the establishment of special lines of work for the training

of hospital dietitians, and the avoidance of courses that duplicate the work at the agricultural college in the preparation of high school teachers; the provision in the near future at the agricultural college of enlarged accommodations for the department of home economics, of opportunities for preparation in institutional and cafeterial management, and of special courses for the preparation of trade and industrial school teachers; the improvement of the accommodations provided for work in home economics at the State Teachers College, and the organization of the department under a single head; the abandonment by the agricultural college of noncollegiate work except for limited short winter, or summer courses for special groups of students and the establishment of corresponding work in selected high schools throughout the State under the direction of the agricultural college; the general reduction of the number of one and two hour courses, especially in elementary work and in the first half of the college year, and of the number of small classes of 10 or under; and the inclusion of the president of the agricultural college in the membership of the board of educational examiners and the inclusion of the presidents of the State higher institutions ex officio in the membership of the State board of education, without power to vote.

Agricultural education in the high schools and common schools of the State, L. S. Hawkins (N. Y. Dept. Agr. Bul. 81 (1916), pp. 1844-1853, pls. 11).—The author briefly explains how the State of New York encourages agricultural instruction in its schools and gives a general description of the agricultural work, particularly the home project work, being done in the 61 high schools and 3 consolidated rural schools that have taken advantage of State aid for agricultural instruction.

Report of the director of elementary agricultural education for the Province of British Columbia, 1914–15, J. W. Gibson (Ann. Rpt. Pub. Schools Brit. Columbia, 44 (1914–15), pp. A74–A85, pls. 4).—This is the first annual report on elementary agricultural education in the Province of British Columbia. It deals with the author's view of agricultural education in the schools, summer schools in rural science for public and high school teachers, including outlines of courses, and with the organization of the first class in high-school agriculture and of an extension class in agriculture in connection therewith for young men not attending school.

Report of the director of elementary agricultural education for the Province of British Columbia, 1915–16, J. W. Gibson (Ann. Rpt. Pub. Schools Brit. Columbia, 45 (1915–16), pp. A54–A71, pls. 10).—This is a report on the history and development of agricultural teaching in British Columbia, progress of the school home gardening movement under the direction of the education department, school-ground improvement, agricultural instruction in high schools with district supervision, including an outline of the two-year course of study by months, and extension high school classes in agriculture for young men and boys over 15 years of age who are not in attendance at school. Plans of school gardens are included.

In 1915, of 100 schools with gardens, 80 qualified for the department grant. In these 80 schools the gardening work was conducted by 115 teachers with approximately 2,500 children. The total grant to the school boards on account of school garden expenditures in 1915 was \$4,052.11 and to teachers, as bonus grants, \$1,765.00. In 1916, 145 schools with gardens and 6,563 pupils took part in the work.

Special grants, regulations, and organization (Dept. Ed. Alberta, Tech. Ed. Bul. 1, pp. 6).—This bulletin contains the regulations pertaining to the payment of grants for instruction in science, agriculture, and school gardening,

manual training, household science and art, etc., and to the training and certification of teachers of these subjects.

For instruction in science, agriculture, and school gardening in rural and village school districts an annual grant is made to the school board equal to 50 per cent of its expenditure for approved improvements and maintenance of school gardens, and not exceeding \$15 for approved equipment, with an annual grant of \$25 to the teacher. In any school district including a town or city in which fewer than 30 teachers are employed in instruction in science, agriculture, and related school gardening in grades 7 to 11, inclusive, or all of such grades as may be represented in such schools, a similar grant of 50 per cent is made to the board, a maximum grant of \$75 for equipment, and \$50 to the teacher for full-time service. In a similar district in which at least 30 teachers are employed in the agricultural course of grade 11 the annual grant to the board is 50 per cent of its expenditure on approved improvements and maintenance of the necessary garden and experimental plats and for equipment, \$75.

The general direction of agricultural instruction, T. Amadeo (Min. Agr. Argentina, Mem. Cong. Nac., 1914, pp. 91-101).—This is a report on the object, work, equipment, and improvements of the agricultural schools and on extension activities in Argentina in 1914.

Agricultural and rural extension schools in Ireland, A. C. Monahan (U. S. Bur. Ed. Bul. 41 (1916), pp. 38, pls. 10).—This bulletin contains a brief account of the administration of public education in Ireland through the Commissioners of National Education, the Intermediate Board of Commissioners, and the Department of Agriculture and Technical Instruction for Ireland, together with information concerning the organization of the department and a brief outline of its activities. Descriptions of the principal types of agricultural schools are included.

In progression from the lower to the higher, there are for men three agricultural station schools or farm apprenticeship institutions and three other agricultural schools, the Albert Agricultural College, which is a farm-practice school giving a one-year course, and the Royal College of Science, with a four-year course, similar to the standard State colleges of agriculture in this country. For women there are nine rural schools of domestic science, the Munster Institute, the Ulster Dairy Institute, the Training School for Lace Teachers, and the Irish Training School of Domestic Economy for the training of teachers. Itinerant instruction in agriculture, through county instructors or agricultural agents, comprises schemes of instruction in poultry keeping and butter making, horticulture and bee keeping, and general instruction in farming in congested districts. There are also rural extension schools or winter classes in agriculture, and, for girls, in poultry keeping and butter making; and, through the division of technical instruction, rural extension schools in household arts, home industries, and farm carpentry.

Agricultural education and live stock improvement in Wales, 1913–1915, C. B. Jones (Bd. Agr. and Fisheries [London], Rpt. Agr. Comr. Wales, 1913–1915, pp. 39).—This is the report of the agricultural commissioner for Wales for the years 1912–13 to 1914–15. It deals mainly with the progress made in agricultural education, both in regard to the agricultural departments of the colleges and the farm institute scheme in the counties, and live-stock improvement. A summary of the report has been previously noted (E. S. R., 36, p. 495).

Report on the agricultural and housekeeping schools for 1914-15 (Aarsber. Offentl. Foranst. Landbr. Fremme, 1915, II, pp. VIII+339).—Detailed reports are given on the faculty, students, equipment, instruction, farm work,

and receipts and expenditures of the agricultural and housekeeping schools in Norway.

Report of the Department of Agriculture [of Finland] for 1914 (Landtbr. Styr. Meddel. [Finland], No. 105 (1914), pp. 165).—This is a comprehensive report on the activities of the department, through its education and research institutions, societies, and experts, for the advancement of Finnish agriculture.

Agricultural yearbook for 1917, edited by H. C. LARSEN (Landökonom. Aarbog [Copenhagen], 18 (1917), pp. 135).—This is the annual directory of public institutions and associations for the advancement of Danish agriculture in its various branches. A list of periodicals published in Denmark is appended.

Bulletin relating to instruction in agriculture and gardening in elementary schools (Edmonton, Alberta: Dept. Ed., pp. 125, pl. 1, flgs. 30).—This bulletin contains a schedule of grants to the school board and teacher for instruction in science, agriculture, and school gardening, an outline of the course in agriculture and gardening required in the seventh and eighth grades, and detailed suggestions to teachers regarding the method of teaching the subjects of soils and plants, including textbook work, practical exercises, and school and home gardening. Nature study and elementary gardening are required in grades 1 to 6, inclusive, in all schools, and agriculture is an examination subject in grade 11.

Course in agriculture for grade XI (Edmonton, Alberta: Dept. Ed., 1915, pp. 9).—This is an outline of a course in agriculture for grade 11 of the Alberta high schools, on which the 1916 examination was based.

Instructions to teachers and school boards with reference to school and home gardening (Brit. Columbia Dept. Ed. Circ. 4 (rev. and enl.) (1917), pp. 15).—This circular contains instructions to teachers and school boards with reference to school and home-garden plans; projects involving experimental work in the variety and condition of seed, prevention of disease, selection, methods of seeding and cultivation, and fertilizers; supplementary home projects where pupils find it difficult or impossible to have home gardens; and competitions and care of school gardens during the summer holidays. A statement concerning grants to school boards toward approved school gardens and home gardening or related home projects, as well as teachers' bonus grants, is included.

Home and school gardening, J. E. McLarty et al. (Agr. Gaz. Canada, 4 (1917), No. 3, pp. 220-231, figs. 3).—This is a series of articles on the relative educational value of school and home gardens, based on the experience with these two forms of gardens of the officials in charge of this work in Prince Edward Island, Nova Scotia, New Brunswick, Quebec, Ontario, Manitoba, Saskatchewan, Alberta, and British Columbia.

In Prince Edward Island it is agreed that under ideal conditions the location of the garden at the school is the more satisfactory. However, the Department of Education is encouraging home gardens at least until a system of consolidated schools is established. In Nova Scotia school gardens are a failure, but home gardens are popular. In New Brunswick, Quebec, southern Saskatchewan, and Alberta it is found that class-room instruction, the observation, demonstration and investigation of the school garden (as the laboratory), and the home garden or project (the practical field) which is the natural outgrowth of these two features, are all necessary in an adequate plan for effective instruction in practical agriculture. In northern Saskatchewan the relative value of the two kinds of gardens has not been demonstrated, but the director of school agriculture is of the opinion that for the earlier grades, school gardening, and for the higher grades, a combination of school and home gardens

with the latter predominating in the final year, would appear almost ideal. In British Columbia the school garden is found to have important advantages over the home garden, but home gardening is deemed best suited to pupils of grades 7 and 8 or form 4. In other words, school gardening, which is more the broadly educational in its bearing, is the logical antecedent of home gardening, which is rather narrower in its scope and which as a rule makes larger demands upon the individual pupil.

Attention is called to the danger becoming apparent in Canada of regarding home gardening and related agricultural home projects as a preparation upon the part of pupils for the holding of a large and sensational school fair, the success of which is too apt to be estimated in the number of entries and the size of the crowd, whereas it should be only an incident in the year's work to arouse an interest among the people and the children themselves. Scores to be taken into consideration in awarding prizes at school fairs to overcome the tendency of making the winning of distinction the chief incentive of the work are also discussed.

School and home gardening for elementary schools in Oregon, M. O. Evans, Jr. (Oreg. Agr. Col. Bul. 176, pp. 23, figs. 22).—The author offers suggestions on the organization and cultivation of school and home gardens for elementary schools in Oregon.

Educative and economic possibilities of school-directed home gardening in Richmond, Ind., J. L. RANDALL (U. S. Bur. Ed. Bul. 6 (1917), pp. 25, pls. 4).—This bulletin contains a report of a study, made in cooperation with the Indiana vocational education survey, of the possibilities of home gardening directed by the public schools in the city of Richmond, Ind.

It is recommended that the Board of Education of Richmond establish a complete department of home gardening under the direction of the public schools within the next three years. The aims should be to train many people to produce their own vegetables and small fruit foods, and to carry out other avocational home projects which may have economic value to the people of the city. A vocational agricultural course should be given for high school students from the country and for those of the city who wish to take up farming as a life work. The course should be given by a teacher with theoretical and practical training in agriculture, who should be employed for twelve months and should also be the general home garden supervisor, giving one-half of his time to the high school work.

Supervised home project work, Z. M. SMITH (Dept. Pub. Instr. [Ind.], Ed. Pubs., Bul. 19 (1917), pp. 44, figs. 24).—This is a report on the project work in Indiana during the past year, including the larger purpose of this work, the income and profit, how the results were accomplished, and the value of close supervision and of county agents as supervisors. Suggestions are offered on organization for home project work and school credit for such work. A suggested list of projects, outlines of projects, a basis of awards for use in annual exhibit contests, and a list of references to literature for use in home project and club work are included.

Supplementary lessons in West Virginia agriculture (Morgantown: W. Va. Univ. [1916, pp. 157, figs. 35]).—This is a bound collection of all the boys' corn, potato, pig. and poultry club, and girls' tomato, strawberry, and raspberry club instruction sheets, accompanied by directions to teachers on the use of the sheets in making the instruction in agriculture in the rural schools of the State more practical and concrete. Suggestions for correlations with other school subjects are included.

Illustrated lecture on sweet potatoes: Culture and storage, H. M. CONOLLY (U. S. Dept. Agr., States Relat. Serv. Syllabus 26 (1917), pp. 22).—This syllabus deals with the raising of sweet potatoes, including a discussion of soils, rotations, propagation of plants, manures and fertilizers, preparation of the soil, planting, harvesting, storage, diseases, varieties, marketing, cost of production, and sweet potatoes as a feed for live stock. A list of 51 lantern slides to illustrate the syllabus is included.

Illustrated lecture on the farm vegetable garden, H. C. Thompson and H. M. Conolly (U. S. Dept. Agr., States Relat. Serv. Syllabus 27 (1917), pp. 15).—In this syllabus, prepared in cooperation with the Bureau of Plant Industry, the authors briefly discuss reasons for establishing a vegetable garden, its location, soil and plan, seed, methods of planting, establishing the garden, cultivation, irrigation, control of insects and diseases, special practices, etc. A list of 50 lantern slides to illustrate the syllabus is appended.

Agricultural arithmetic, G. C. Shutts and W. W. Weir (St. Paul, Minn.: Webb Publishing Co., 1916, pp. 255+10, figs. 54).—Part 1 of this book is devoted to a review of the processes of arithmetic. Part 2 is an application of arithmetic to farm experiences, including problems dealing with farm crops and animals, feeds and feeding, the dairy, the soil, fertilizers, farm management and measurements, orchard and garden, household economy and human feeding, etc.

Illustrative fair exhibits, F. M. Lutts (Ohio Sta. [Pub.], 1917, Feb., pp. 27, figs. 27).—This gives the earlier history of the illustrative fair exhibits of the Ohio Station; brief descriptions of the State fair exhibit and of the county fair exhibits, the latter representing nine station departments; information with reference to exhibit assignments, publicity, memorandum of understanding between the station and fair association, and the bill of material; and a summary of fair exhibit work in 1916.

## MISCELLANEOUS.

Annual Reports of the Department of Agriculture, 1916 (U. S. Dept. Agr. Rpts. 1916, pp. VI+451).—This contains the reports of the Secretary and heads of bureaus and other administrative officers. The various reports are also issued as separates. Sections dealing with roundworms of sheep and the food supply of the United States are abstracted on pages 277 and 289 of this issue.

Twenty-ninth Annual Report of Illinois Station, 1916 (*Illinois Sta. Rpt. 1916*, pp. 18).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1916, brief notes as to the principal lines of work, a note commemorative of the work of the late Dr. T. J. Burrill, and a list of the publications of the year.

Twenty-fourth Annual Report of Minnesota Station, 1916 (Minnesota Sta. Rpt. 1916, pp. 83).—This contains the organization list, a financial statement for the Federal funds for the fiscal year ended June 30, 1916, and for the State funds for the fiscal year ended July 31, 1916, and a report of the director summarizing the work of the station and its substations. The experimental work recorded is for the most part abstracted elsewhere in this issue.

Report of the superintendent, Northwest Experiment Station, 1910-1916 (Minnesota Sta., Rpt. Crookston Substa., 1910-1916, pp. 102, pl. 1, figs. 14).—This contains the organization list and a report of the superintendent of the

substation from 1911 to 1916, including several special articles by members of the staff. The experimental work reported is for the most part abstracted elsewhere in this issue.

Reports of Northeast Demonstration Farm and Experiment Station, Duluth, 1915 and 1916 (Minnesota Sta., Rpts. Duluth Substa., 1915, pp. 11. fig. 1; 1916, pp. 12).—These are reports of the work of the respective years. The experimental work reported is for the most part abstracted elsewhere in this issue.

Report of West Central substation, Morris, 1915 (Minnesota Sta., Rpt. Morris Substa., 1915, pp. 15, figs. 3).—This is a report of the work of the year. The experimental work with field crops is abstracted on page 229 of this issue.

Twenty-ninth Annual Report of New York Cornell Station, 1916 (New York Cornell Sta. Rpt. 1916, pp. LXXXVIII+832, pls. 41, figs. 145).—This contains the organization list, reports of the director of the station and heads of departments, and reprints of Bulletins 362-377 and Circular 32, previously noted.

Report of the Porto Rico Insular Station, 1915–16 (*Rpt. Bd. Comrs. Agr. P. R.*, 5 (1915–16), pp. 101, pl. 1, figs. 3).—This contains the organization list, a report by the director for the fiscal year 1915–16, and departmental reports, the experimental features of which are for the most part abstracted elsewhere in this issue. Analyses of soils are also included.

Monthly Bulletin of the Ohio Experiment Station (Mo. Bul. Ohio Sta., 2 (1917), No. 4, pp. 103-137, figs. 15).—This contains several articles abstracted elsewhere in this issue, together with the following: Post Timbers, by J. J. Crumley, an abstract of Bulletin 219 (E. S. R., 24, p. 644); Soil Bacteria, by E. R. Allen; and notes.

# NOTES.

Alabama Canebrake Station.—A canning demonstration was held at the station July 20, in cooperation with the State extension forces. The total attendance for the day was about two hundred.

Iowa College and Station.—George M. Turpin, head of the poultry section, resigned June 30 to engage in practical poultry work, and has been succeeded by H. A. Bittenbender, formerly in extension work at the college.

Kansas Station.—A cooperative study to determine the value of sweet clover as a pasture crop for dairy cows has been begun by the departments of agronomy and dairy husbandry.

S. J. Pearce, a 1917 graduate of the University of Nebraska, began work July 1 at Herington as field dairy bacteriologist for the station in connection with a study in cream grading in progress at that point, in cooperation with the Dairy Division of the U. S. Department of Agriculture. M. W. Kirkpatrick, formerly superintendent of the Dodge City substation, has been appointed superintendent of the Tribune substation to succeed C. E. Cassel, resigned.

Minnesota University.—The university stock barn erected in 1886 was entirely destroyed by fire July 18, causing an estimated loss of about \$40,000. All live stock was saved, but a considerable amount of machinery and supplies was consumed. The cause is thought to have been a spark from a motor in the feedgrinding room.

Montana Station.—Ray S. Jones, assistant chemist, resigned May 1 to join the U. S. Officers Reserve Corps. He has been granted leave of absence until the end of the war.

Cornell University.—Dr. V. A. Moore, director of the New York State Veterinary College, has been appointed major in the Veterinary Corps of the U. S. Army.

New York State Station.—Substantial progress is being made in the construction of the new \$100,000 administration building, auditorium, and museum, although it is regarded as doubtful whether it will be ready for occupancy before the summer of 1918.

Irving Rouse of Rochester and C. Fred Boshart of Lowville have been appointed to the board of control, vice Thomas Newbold and William H. Manning, J. F. Barker, agronomist, has resigned to accept a position in charge of extension work in agronomy at the Ohio State University, and will be succeeded by R. C. Collison, associate chemist, on September 1. Mr. Collison has also been granted a year's leave of absence for study, beginning with the next college year. W. W. Baer, assistant chemist, has entered the U. S. Naval Service.

Oregon College and Station.—A horticultural products building is being erected to aid in solving some of the many problems of food preservation confronting the department of horticulture. Many types of drying and canning equipment will be installed, including a modern evaporator of commercial capacity.

Dean A. B. Cordley has been elected chairman of the State Lime Board, which is to obtain lime for the use of farmers.

Porto Rico Federal Station.—The Porto Rico legislature, at its last session, appropriated \$1,000,000 for aid in the growing of food crops and an extensive campaign is under way. About forty rural teachers are actively engaged in all sections of the island and a great many seeds of economic crops have been bought and distributed. Cane planters have been induced to plant or to allow their laborers to grow beans in the young cane, so that whereas last year over \$800,000 worth of beans was imported, beans have already been produced for export.

Rhode Island Station.—Howard A. Johns, a 1917 graduate of the Pennsylvania College, has been appointed assistant in chemistry beginning July 1.

South Carolina College and Station.—The animal husbandry and dairying division has been separated into divisions of dairying and animal husbandry. R. L. Shields continues as chief of the animal husbandry division and W. W. Fitzpatrick, dairy expert in extension work, has been appointed chief of the division of dairying.

G. M. Armstrong has been appointed instructor in botany in the college and assistant in the station. A new position of research assistant has been established in the division of horticulture.

Tennessee University.—H. D. Tate has been succeeded by W. A. Schoenfeld as assistant director of the division of extension, and he in turn by C. E. Brehm as specialist in marketing.

Utah College and Station.—Plans have been completed for the new dairy building and are under way for some new feeding sheds for experimental work with steers. Dr. C. E. Davis has resigned as assistant professor of chemistry to accept a position as research chemist with a commercial firm.

Virginia College and Station.—E. R. Hodgson, associate agronomist, has resigned to become specialist in agronomy in the extension division and has been succeeded by T. K. Wolfe, the assistant agronomist. G. S. Ralston has been appointed field horticulturist, to have charge of the several experimental orchards in the State.

Wyoming University and Station.—W. A. Albrecht, of the Missouri University and Station, has been apopinted associate agronomist and acting head of the department of agronomy, beginning July 1.

# EXPERIMENT STATION RECORD.

Vol. 37.

SEPTEMBER, 1917.

No. 4.

The passage of the Federal Food Production Act has added to the list of war measures an enactment of direct interest to agriculture. It constitutes a tangible recognition by Congress of the exceptional importance attached to the maintenance of an ample food supply as a strategic phase of the present conflict, and of the consequent need of fostering production on the farm and conservation in the home through Federal aid to an extent never before attempted. It materially increases the funds at the disposal of the Federal Department of Agriculture and enlarges its powers and functions in a number of directions during the national emergency.

The responsibility resting upon the agricultural interests of the country to develop food production was pointed out by President Wilson soon after the outbreak of hostilities. In his address to the American people of April 15, the President said:

"The supreme need of our own Nation and for the nations with which we are cooperating is an abundance of supplies and especially of foodstuffs. The importance of an adequate food supply, especially for the present year, is superlative. Without abundant food, alike for the armies and the peoples now at war, the whole great enterprise upon which we have embarked will break down and fail. The world's food reserves are low. Not only during the present emergency but for some time after peace shall have come both our own people and a large proportion of the people of Europe must rely upon the harvests in America. Upon the farmers of this country, therefore, in large measure rests the fate of the war and the fate of the nations."

An agricultural mobilization of huge proportions followed the declaration of a state of war. The resources of the Federal Department of Agriculture, the agricultural colleges and experiment stations, and many other agencies were concentrated so far as possible upon the emergency situation with a view to rendering all possible assistance. The campaign to increase production which followed has been without precedent in its magnitude and comprehensiveness, its resourcefulness, and its spirit of intelligent leadership and service. The results have already demonstrated in convincing fashion what important assets these institutions have become in the Nation's re-

sources, as well as some of their potentialities for the days still to come.

The activities of the Department of Agriculture, which is administered mainly on a basis of annual appropriations, are at all times quite closely prescribed in advance by the terms of existing legislation. When the United States entered the war, routine appropriation acts had already been adopted covering its work up to June 30, 1918. This legislation had of course been framed when the Nation was still at peace, so that the passage of emergency legislation became necessary to meet the altered conditions.

A number of measures designed to supplement the resources of the Department were introduced into Congress, among them the act under review. This law was passed by the House of Representatives May 28, and with numerous amendments by the Senate June 2. It was hoped that the measure would become law prior to the beginning of the new fiscal year on July 1, but it was not until August 2 that it was reported from conference, and it was on August 10 that it was signed by President Wilson. On the same day was signed the so-called Food Control Act, an entirely separate measure having to do chiefly with the regulation of the distribution of foods, feeds, fuel including fuel oil and natural gas, and fertilizer and fertilizer ingredients, tools, utensils, implements, machinery, and equipment required for the actual production of foods, feeds, and fuel. This measure is likewise intimately related to agriculture, but it is not administered by the Department of Agriculture and no editorial discussion of it is here attempted. A description of its main provisions may be found elsewhere in this issue (p. 399).

The Food Production Act, as stated in its opening section, is "for the purpose of more effectually providing for the national security and defense and carrying on the war with Germany by gathering authoritative information concerning the food supply, by increasing production, by preventing waste of the food supply, by regulating the distribution thereof, and by such other means and methods as are hereinafter provided." It is thus primarily a war measure. Its duration is restricted to the termination of the national emergency resulting from the existing state of war, as determined by the President, but not later than the beginning of the next fiscal year after the ending of the war. During this period certain functions of the Government are enlarged and extended, and the President is authorized to direct any agency or organization of the Government to cooperate with the Secretary of Agriculture in carrying out the purposes of the act and to coordinate their activities so as to avoid any preventable loss or duplication of work. In addition, the Secretary

is authorized "to cooperate with such State and local officials, and with such public and private agencies or persons, as he finds necessary."

The appropriations contained in the act are made for the period ending June 30, 1918. They thus supplement those carried in previous appropriations for this period, a summary of which has already appeared in these columns.1

The aggregate amount carried by the act is \$11,346,400. This is not a large sum as compared with many of the emergency appropriations. The Food Control Act, for instance, appropriates \$162,500,000, of which \$10,000,000 is placed at the disposal of the President for the purchase and sale of nitrate of soda under certain conditions for agricultural production. None the less, it represents a total substantially equivalent to that carried in the regular appropriation act for the Department for the fiscal year 1908, and is larger than that for the Department for the fiscal year 1908, and is larger than that for any earlier year. It increases the total funds for the Department's work to \$55,160,513, of which \$26,579,113 is carried in routine appropriation acts, and \$17,235,000 as permanent and indefinite appropriations, chiefly under the Federal-aid Road Act, the meat-inspection provision, and the Extension Act. As compared with the preceding fiscal year, this constitutes a net increase of \$20,007,661.

The principal items of expenditure authorized are for educational and demonstration work, food surveys, marketing and distribution studies and advice, the procuring and sale of seeds, aiding in the supply of farm labor, stimulating live stock production, combating insect pests and plant and animal diseases, and promoting the conservation and utilization of plant and animal products. Most of the projects provided for will be an extension of present activities on a larger scale, but some will represent new undertakings.

The largest single appropriation is \$4,348,400 for increasing food production and promoting the conservation of food by extension teaching and demonstration through country, district, and urban Federal funds for these purposes, the annual appropriations to the States Relations Servive for cooperative demonstration work for the year aggregating \$1,237,800 and the appropriations under the Extension Act \$2,080,000. It is expected to use the increased funds largely for county agents, home demonstration, and boys' and girls' club work.

Plans have been made to expand immediately the cooperative extension work of the Department and the State agricultural colleges by a large increase in the number of county agricultural agents and home demonstration agents. Approximately fourteen hundred men and five hundred women are at present employed, and the number

to be added will depend in large degree upon the number of trained men and women available. The plans formulated contemplate the extension of the male county agent work to all rural counties of the Union in which there is a need for it, and the placing of an additional agent in some of the larger counties already organized. They also contemplate a considerable increase in the number of women agents engaged in extension activities, including the placing of these agents in the larger towns and cities for the first time. The use of urban agents is deemed especially desirable because of the importance attached in the present crisis to the conservation and efficient utilization of foods. These agents will work mainly in cooperation with existing organizations of women, stimulating the production of garden truck, poultry, and other products by women and children, as well as the promotion of economy in the purchase and use of food and methods of food conservation by canning, drying. etc.

The States Relations Service will also seek to enlarge materially the enrollment of young people in the boys' and girls' clubs, which are devoted to increasing agricultural production and conserving the food supply. Opportunity for additional assistance is likewise afforded to the Office of Home Economics, which plans to work out problems in the efficient utilization of various foods and prepare popular bulletins on diet and food conservation.

The funds at the disposal of the Bureau of Markets, which receives \$1,718,575 in the current appropriation act, will be more than doubled by the emergency appropriation, which provides \$2,522,000 for work along this line. The Secretary of Agriculture, with the approval of the President, is given very broad authority to ascertain conditions relating to food and agricultural supplies. This contemplates not only data as to the demand, the supply, consumption, costs, and prices of food, but also the basic facts relating to the ownership, production, transportation, manufacture, storage, and distribution of foods. The authority applies likewise to food materials, feeds, seeds, fertilizers, agricultural implements and machinery, and indeed to any article required in connection with the production, distribution, or utilization of food.

A quick survey carried on chiefly by the Bureaus of Markets, Crop Estimates, and Chemistry, and the States Relations Service as to the existing food situation is projected, and a system of monthly reports and, if needed, additional surveys are also under consideration. The object will be to ascertain as accurately as possible the status of the country's food and feed supply from the farm to the consumer, including data as to the normal consumption, as a basis for rational production and conservation. Additional legal authority is given for obtaining the necessary information, and wilful failure to supply

this is made a misdemeanor punishable by fine or imprisonment or both.

Provision is made for further extending the market news service of the Department to include grain, hay, seeds, and dairy and poultry products, and to supply additional information as to the marketing, movement, and distribution of perishable products. Steps to decrease waste of food in storage or during transit and sale are also contemplated, such as the working out of improved methods of packing and handling. The Department is empowered to examine and certify to shippers the condition as to soundness of fruits, vegetables, and other food products when received at important central markets designated by the Secretary of Agriculture, and it is provided that these certificates will be received as prima facie evidence in the courts. It is anticipated that this inspection service, among other benefits, will tend to inspire confidence in the minds of producers and so increase shipments of perishable commodities.

An appropriation of \$885,000 is made for additional work relating to the meat supply. Enlarged production of hogs and poultry is the special object to be sought, since these are the two live-stock products capable of most rapid increase. The pig and poultry clubs are to be further developed and specialists added in the principal States. The further development of dairying and the better utilization of dairy products are also to be fostered. Efforts will likewise be made to increase animal production indirectly by extending the campaign against animal diseases and pests, especially hog cholera, the cattle tick, and tuberculosis.

For the combating of insect pests and plant diseases and the conservation and utilization of plant products \$441,000 is appropriated. Special efforts are to be made to disseminate knowledge of methods of insect and plant disease prevention and control through demonstrations, the supplying of specialists in case of serious outbreaks, and in similar ways. One phase of the entomological work to receive increased attention is that dealing with insect infestations of stored products, a separate division for which has been recently established in the Bureau of Entomology. Black rust of wheat, grain smut, and the diseases of potatoes, beans, and truck crops are to receive special prominence in the Bureau of Plant Industry, which will also seek to stimulate conservation of food products by demonstrating proper methods of storing such crops as may be kept in common storage, by improving the methods of storage, and otherwise.

In order to overcome a possible shortage of seed in localized areas, authority is given the Department, whenever an acute need arises

in such areas for seeds of food or feed crops, to purchase seeds or contract with persons to grow them, and to sell the seed to farmers for cash at the cost price plus the expense of packing and transportation. An appropriation of \$2,500,000 is made for this work, which may be used as a revolving fund until June 30, 1918.

An allotment of \$650,000 is made for miscellaneous purposes. Among these an item of special interest is that of aiding agencies in the various States in supplying farm labor. For some time the Office of Farm Management has been cooperating with the Federal Department of Labor in endeavoring to bring about better organization of the labor remaining on farms and to call into service available labor which heretofore has not been fully or regularly utilized in farming operations. Representatives have been detailed to cooperate with the State officials in charge of labor matters, the agricultural colleges, county agents, and county or local labor committees or representatives. The increased funds now made available will enable the extension of this undertaking.

Provision is made for enlarging the informational work of the Department, including the distribution of large editions of emergency leaflets, posters, and the like. Additional work in crop estimating is also provided, both for assisting in the nation-wide food survey already referred to and for an enlarged service along lines previously in progress.

The enormous increase in the amount of administrative work of the Department in recent years is recognized in the authorization for the appointment by the President, subject to confirmation by the Senate, of two additional Assistant Secretaries of Agriculture. Under this provision, Prof. Clarence Ousley, director of the extension service of the A. & M. College of Texas, and President Raymond A. Pearson of the Iowa State College have been appointed to these positions.

Appended to the act are three sections affecting existing permanent legislation. One of these amends the Meat Inspection Act of 1890, by authorizing, under certain restrictions and at the discretion of the Secretary of Agriculture, the admission for immediate slaughter at points of entry below the southern cattle quarantine line of tick-infested cattle otherwise free from disease. The purpose of this amendment is to increase the meat supply through importations of live cattle from Mexico, South and Central America, and the islands of the Gulf of Mexico and the Caribbean Sea.

An amendment to the Enlarged Homestead Act of 1910 increases from 320,000 to 1,000,000 acres the amount of land available for entry in Idaho and renders less rigorous certain requirements for residence thereon. Under the third amendment, the Secretary of the Interior is authorized at his discretion to suspend certain

residence requirements of the Reclamation Act with reference to the supplying of irrigation water.

The Food Production Act thus provides for the rendering of assistance by the Department of Agriculture on a larger scale and along lines of broader scope than ever before. Despite the fact that the bill did not become a law until the crop season of 1917 was past its zenith, and other difficulties inherent in the rapid organization of so great an expansion of work, a comprehensive program has been formulated and the increased activities provided are being vigorously undertaken. It is believed that if the campaign projected is successful, and the American people respond as expected, a marked contribution will have been made to the national efficiency and economy. Moreover, the results should be of assistance not only in the existing emergency but should possess considerable residual value of permanent advantage to the Nation.

# RECENT WORK IN AGRICULTURAL SCIENCE.

## AGRICULTURAL CHEMISTRY-AGROTECHNY.

A method for the separation of the dietary essential, "fat-soluble A," from butter fat, E. V. McCollum, Nina Simmonds, and H. Steenbock (Jour. Biol. Chem., 29 (1917), No. 2, p. XXVI).—The authors, at the Wisconsin Experiment Station, conducted feeding experiments in which milk fat which had been melted and thoroughly agitated with 20 successive portions of water was used. After this treatment it was found to be no longer effective in producing growth when fed with suitably constituted diets. Change to unwashed milk fat was followed by a prompt resumption of growth.

Antineuritic substances from egg yolk, H. Steenbock (Jour. Biol. Chem., 29 (1917), No. 2, p. XXVII).—The author, at the Wisconsin Experiment Station, notes the preparation of an acetone-soluble fraction from egg yolk which in small doses by intraperitoneal injection was able to cure a pigeon suffering from polyneuritis. The antineuritic substance was found to be stable to concentrated hydrochloric acid at 98° C. and to concentrated alkalis at room temperature, but was readily destroyed by dilute alkalis at boiling temperature. It was incompletely precipitated by phosphotungstic acid. It is indicated that it was not adenin.

Adenin and guanin in cows' milk, C. Voestlin and C. P. Sherwin (Jour. Biol. Chem., 29 (1917), No. 2, p. VI).—From 100 liters of a mixed sample of cows' milk the authors isolated 500 mg. of adenin and 100 mg. of guanin by means of silver precipitation of the protein-free residue.

Calcium and phosphorus in the blood of lactating cows, E. B. Meigs and N. R. Blatherwick (*Jour. Biol. Chem.*, 29 (1917), No. 2, pp. XI, XII).—Calcium, nitrogen, total phosphorus, and lipoid and inorganic phosphorus have been determined in the blood and plasma of cows and heifers of various ages on various rations and at various stages of pregnancy and lactation.

The calcium content of cow's plasma was found to be surprisingly constant, the highest figure obtained being 0.0114 per cent and the lowest, 0.0086 per cent. The results indicate that the amount is not appreciably altered by pregnancy, lactation, or considerable changes in diet.

The total, lipoid, and inorganic phosphorus contents of normal plasma were found to be extremely variable. The total phosphorus varied from 0.0085 to 0.0178 per cent; the lipoid, from a little less than 0.002 to a little over 0.008 per cent; and the inorganic, from about 0.004 to 0.008 per cent. In general the variations of inorganic phosphorus appeared to depend to some extent on the amount of grain fed. No tabulated data are submitted.

The distribution of esterases in the animal body, Agnes E. Porter (Biochem. Jour., 10 (1916), No. 4, pp. 523-533).—Fat- and wax-splitting ferments were found to be widely distributed among the organs of man, ox, sheep. goat, pig, cat, rabbit, and guinea pig. Butyrinase and lecithase were present in all of the organs examined. Olein lipase was also commonly present, but often only as a mere trace. It appeared to be strongest in pig's pancreas but

was also active in the pancreas of other species, in the liver and in the thymus, and to a lesser degree in the lymphatic glands, ox suprarenals and thyroid, cat kidney, and pig lung. Tristearin was also frequently found. Wax-splitting enzyms were found in ox, sheep, and pig pancreas, human, ox, pig, cat, and rabbit liver, thymus, and lymphatic glands, ox and sheep thyroid, or suprarenals, human skin, and cat and human kidney.

"The distribution of esterases in the body appears to have some relation to resistance to tubercle. The cat, which is very little susceptible to tubercle, is well provided with esterases throughout its organs. The sheep, although less well-provided for than the susceptible pig in other regions, possesses very active lymphatic glands. The susceptible guinea pig has the chief part of its lipase in the form of butyrinase and olein lipase, and is deficient in higher esterases. The lungs in all species were found very poor in these ferments. The more resistant liver showed active lipolytic properties."

The experimental procedures used and the data obtained are described and submitted in detail.

The nonspecificity of animal and vegetable reductase, A. Bach (Compt. Rend. Acad. Sci. [Paris], 164 (1917), No. 5, pp. 248, 249).—From data obtained in a study with 14 different aldehydes in the reduction of nitrate by reductase (of milk and potato) in the presence of an aldehyde the author concludes that the specificity of the reducing ferment is functional and not structural. The specificity is considered to depend on a determined chemical function and not on any geometrical configuration.

The composition of adipocere, R. F. RUTTAN and M. J. MARSHALL (Jour. Biol. Chem., 29 (1917), No. 2, pp. 319–327).—The following percentage composition of a sample of adipocere found near Rockburn, Quebec, is reported: Palmitic acid, 67.52; stearic acid, 3.3; oleic acid, 5.24; l-hydroxy stearic acid, 9.48; θ-hydroxy stearic acid, 6.32; stearin and palmitin, 1.21; olein, 0.16; unsaponified matter, 0.87; calcium soaps, 4.41; protein, 0.665; ash, 0.578; humus and undetermined, 0.247. The physical and chemical constants of the ether-soluble matter found were specific gravity at 100° C., 0.8436; refractive index at 65°, 1.436; melting point, 60 to 63°; acid value, 201.7; saponification value, 207; iodin value, 6.04; and acetyl value, 34.75.

The data are discussed.

The isolation of stachydrin from alfalfa hay, H. Steenbock (Jour. Biol. Chem., 29 (1917), No. 2, p. XXVII).—The author at the Wisconsin Experiment Station notes the isolation of l-stachydrin in a pure form and as the hydrochlorid from the phosphotungstic acid fraction of the water-soluble constituents of alfalfa hay. It was identified by the preparation of the picrate, chloroplatinate, aurate, methyl ester, and methyl ester chloroaurate, all of which were found to be characteristic. It is indicated that "the Kossel and Van Slyke methods when applied directly to alfalfa hay nitrogen give erroneous values for the diamino acids, the error in the first case falling upon the lysin fraction and in the second case upon the histidin fraction."

The pectic substances of plants.—Preliminary communication, S. B. Schryver and Dorothy Haynes (Biochem. Jour., 10 (1916), No. 4, pp. 539-547).—A procedure for the preparation of the pectic substances of plants which consists essentially of extracting the residue, obtained after expressing the juice, with a warm 0.5 per cent ammonium oxalate solution and precipitation with alcohol is described in detail. The substance so obtained was acidic in character, soluble in water, and designated by the authors as pectinogen. It was purified, usually in small quantities, by dissolving in water to make a 3 to 4 per cent solution, centrifugalizing, and precipitating the clear fluid by alcohol. The precipitate was filtered, washed, air dried, and obtained in the

form of a granular white powder. The largest amount of this preparation was obtained from turnips, but preparations were also obtained from strawberries, apples, and rhubarb stems.

An alkaline solution of the pectinogen kept at room temperature was readily converted into another substance of acidic character which could be precipitated from alkaline solutions by acids as a gel insoluble in water. This substance has been designated as pectin. It is insoluble in water and the solution of its sodium salt gives a gelatinous precipitate with calcium chlorid.

The analyses of the pectins obtained from the various sources agree well with the formula  $C_{17}H_{24}O_{14}$ . On distillation with hydrochloric acid the pectinogin yielded furfural in such quantity as to indicate the presence of one pentose group in each complex of 17 carbon atoms. It is indicated that the results obtained show that "there is a single pectin, which is a complex built up by the combination of a pentose group with another group containing twelve carbon atoms. There is no evidence that it is a carbohydrate, but it appears to be an acid sui generis."

The acids of fruit wines, W. J. Baragiola (Landw. Jahrb. Schweiz, 30 (1916), No. 5, pp. 441-454).—This is a general discussion of the subject, together with some experimental data on the decrease in total acidity with increasing ripeness of the fruit; the decrease of tannic acid with increasing ripeness in the juice pressed from crushed, coarsely ground, and very finely ground fruit; the variation of the amount of tannic acid in the juice from the peel, flesh, and core of pears; and the decrease of tannic acid in the juice from fruit which had been exposed to the air and had consequently undergone some oxidative changes brought about by the oxidases.

The author points out the errors which are likely to arise in drawing conclusions from data obtained from grape wines and applied in the preparation of fruit wines. A complete analysis of a cider is submitted.

It is concluded that in the case of berry wines the acidity of the young wines remains fairly constant because of the large amount of tartaric acid present. The sour taste of grape wine is first markedly influenced by the other organic acids after the greater part of the tartaric acid has been removed. The reverse is the case in fruit wines, where the individual acids in the young wines exercise a marked influence on the general character of the product.

Tartaric acid content of grape musts and young wines, W. J. BARAGIOLA and O. Schuppli (Landw. Jahrb. Schweiz, 30 (1916), No. 5, pp. 455-479).—Detailed analytical data relative to the total acidity, tartaric acid content, and percentage of tartaric acid of the total acidity of musts prepared at the Swiss experiment station at Wädenswil, musts from the private experimental fields in the Canton of Zurich, and a number of wines which were made in 1914 are submitted and briefly discussed.

Investigations on the camphors of Mauritius (Dept. Agr. Mauritius, Sci. Ser., Bul. 4 (1916), [English Ed.], pp. 14).—The results of a number of distillation experiments preliminary to a reforestation of certain parts of the island have shown that the existing camphors yield no solid camphor on distillation. The small amount of camphor present is readily dissolved in the oil and not easily separated therefrom.

Standard methods of chemical analysis, edited by W. W. Scott (New York: D. Van Nostrand Co., 1917, pp. XXXI+864, pls. 3, figs. 142).—As stated in the preface, this volume is a compilation of carefully selected methods of technical analysis that have proved of practical value to the professional chemist. The methods are described in sufficient detail to be easily carried out, but lengthy theoretical discussions have been avoided in order to include a large amount of information in a compact, accessible form.

The material is grouped under three major divisions, (1) quantitative determination of the elements, (2) special subjects, and (3) tables and useful data. In the chapters on the elements the subject matter is treated in a general way under the headings of physical properties, detection, estimation, preparation and solution of the samples, separations, and gravimetric and volumetric methods.

Report of the work of the Swiss Agricultural Chemical Institute at Bern (Liebefeld) for the year 1915, P. LIECHTI (Landw. Jahrb. Schweiz, 30 (1916), No. 5, pp. 489-508).—This report contains the results of the fertilizer and feeding stuff control work and brief notes on some projects being carried on, chiefly in connection with fertilizers.

Standard methods for the examination of water and sewage (Boston: Amer. Pub. Health Assoc., 1917, 3. ed., pp. XVI+115, fig. 1).—This is a revision of the methods by committees of the American Public Health Association and the American Chemical Society and referees of the Association of Official Agricultural Chemists. It includes chemical, microscopical, and bacteriological procedures and a chemical and bacteriological bibliography.

Applications of a new reagent for the separation of ammonia.—I, The colorimetric determination of ammonia in urine, O. Folin and R. D. Bell (Jour. Biol. Chem., 29 (1917), No. 2, pp. 329-335).—On account of the impossibility of obtaining the charcoal used in the method described by Folin and Denis (E. S. R., 36, p. 316), and for which no substitute could be found, the authors have modified the procedure for nitrogen determination by direct nesslerization. The material used in the procedure is a synthetic mineral, an "aluminate silicate," which possesses the peculiar absorptive properties characteristic of some natural zeolites. The crude product is sold under the trade name "permutit."

The modified procedure is as follows: Two gm. of the powder is transferred to a 200-cc. volumetric flask, 5 cc. of water added and, with an Ostwald pipette, 1 or 2 cc. of undiluted or, with a 5-cc. pipette, 5 cc. of diluted urine introduced. The added sample is rinsed down with a little water and the mixture gently but continuously shaken for five minutes. The powder is rinsed to the bottom of the flask with water, and the supernatant liquid decanted. Water is added once more and decanted. A little water is now added to the powder, 5 cc. of 10 per cent sodium hydroxid introduced, the liquid agitated, and water added until the flask is about three-fourths full. It is then shaken for a few seconds, 10 cc. of Nessler's reagent added, the liquid thoroughly mixed, and allowed to stand for 10 minutes or as much longer as may be convenient. It is then filled to the mark with water, mixed, and compared with the standard in the colorimeter.

Experimental data submitted indicate the accuracy of the method.

A note on certain chemical changes in shucked oysters under refrigeration, and methods of detecting these changes, E. D. Clark and L. H. Almy (Jour. Biol. Chem., 29 (1917), No. 2, pp. XXIII, XXIV).—Preliminary experiments showed that freshly shucked oysters standing at temperatures above the freezing point yielded regularly increasing percentages of ammoniacal nitrogen by aeration, amino-acid nitrogen, and reducing substances.

Larger scale studies were made to simulate commercial practices in the handling and transporting of oysters, in which samples were held at different temperatures for various periods of time up to 15 days. During storage the ammoniacal nitrogen showed the most marked increases, but the low temperature of 34° F. had a great inhibiting effect on the production of ammonia. Amino-acid nitrogen and a reducing substance, which is indicated as probably being sugar, did not show increases of the same magnitude as ammonia.

The amino-acid nitrogen was determined by Van Slyke's gasometric procedure and by Sörensen's formol titration method, and the reducing substances by Benedict's quantitative method for sugar.

It is indicated that, "as is the case with all perishable substances, decomposition in oysters is not prevented by low temperatures but is merely retarded, especially at temperatures near the freezing point."

The determination of peanut oil in mixtures with olive oil, R. Biazzo and S. Vigdorcik (Ann. Chim. Appl. [Rome], 6 (1916), No. 9-12, pp. 179-185).—Methods which have been proposed for the determination of peanut oil in mixtures are briefly reviewed.

The method proposed by the author consists of treating the fatty acids obtained from the oil in 200 cc. of ether with 50 cc. of a 30 per cent lead acetate solution. The lead soaps of the liquid fatty acids dissolve in the ether, while the insoluble soaps of the solid acids form an intermediate layer between the aqueous solution and the ether. The clear ethereal solution is decanted through a dry filter, the residue washed with ether, transferred to the filter, and again washed. It is then transferred to a separatory funnel with 200 cc. of ether, the fatty acids liberated with hydrochloric acid, the ethereal layer separated, washed with water, the ether distilled, and the residue dried and finally tested for arachidic acid by the usual tests.

The determination of colza oil in mixtures with olive oil, R. BIAZZO and S. VIGDOBCIK (Ann. Chim. Appl. [Rome], 6 (1916), No. 9-12, pp. 185-195).— Earlier work on the subject is reviewed.

The method proposed by the author depends on the concentration of erucic acid, its conversion into behenic acid, and the identification of the latter. The fatty acids from 20 cc. of the oil are dissolved in 180 cc. of anhydrous acetone, the solution heated to boiling, and treated with 20 cc. normal potassium hydroxid. The precipitated acid potassium soaps are filtered off, washed with acetone, dissolved in water, decomposed with hydrochloric acid, and the fatty acids extracted by ether. The ethereal solution is shaken with lead acetate, and the insoluble lead soaps treated for the determination of arachidic acid as noted above. The soluble lead soaps are decomposed with hydrochloric acid, the free acids separated, and then hydrogenated in the presence of palladium catalyzer. The hydrogenated acids are fractionally crystallized and their melting point determined.

On the determination of theobromin and caffein in cocoa and chocolate, G. Savini (Ann. Chim. Appl. [Rome], 6 (1916), No. 9-12, pp. 247-250).—In the procedure described 12 gm. of the pulverized sample is treated with 70 cc. of petroleum ether in a 500-cc. flask and heated on the water bath for 10 minutes. The liquid is then decanted and the operation repeated with two portions of the solvent.

The defatted material is transferred to a flask and boiled for about one hour with 5 cc. of 10 per cent sulphuric acid and about 250 cc. of water. During the heating the contents are occasionally shaken, and finally made up to volume (300 cc.) at about 30° C, and filtered. Two hundred and fifty cc. of the filtrate (corresponding to 10 gm. of the original substance) is evaporated in a porcelain dish after the addition of magnesia to make the mixture alkaline and 10 gm. of fine sand. When the mass attains a sirupy consistency and about 8 to 10 gm. of magnesia have been added it is allowed to cool, pulverized in the mortar, and extracted with chloroform to which 0.25 cc. of concentrated ammonium hydroxid has been added. The extraction is repeated several times until about 500 cc. of chloroform has been used. The solvent is then removed by distillation. The residue obtained is of sufficient purity to be weighed directly. The

procedure is indicated as being easy to manipulate and to be applicable to a variety of substances.

Some analytical data submitted indicate the accuracy of the procedure.

Detection of lime used as a neutralizer in dairy products, H. J. Wichmann (U. S. Dept. Agr. Bul. 524 (1917), pp. 22).—From an analytical study of the calcium oxid in cream, the total ash and the salt-free (sodium-chlorid-free) ash, 25 per cent calcium oxid in the salt-free ash was found to be a good maximum standard. If the calcium oxid percentage is below 25 it is considered that the butter may be classed as made from unlimed cream, while samples with calcium oxid percentages between 25 and 28 in a salt-free ash should be considered suspicious. In cases of doubt as to the possibilities of the presence of large amounts of calcium sulphate in the salt used, a sulphate determination should be made and the proper correction applied. The effect of calcium chlorid, magnesium chlorid, and sodium sulphate which might be present in the salt used was studied, and the amounts ordinarily present found to have no effect.

The use of lime in renovating old storage butter is noted and briefly discussed. Analytical data of the ash of a number of creams before liming, of butter made from unneutralized cream, of salted and unsalted butters made from unneutralized cream, and of unlimed and limed dairy products are submitted.

The determination of sugar in gummy substances, G. Savini (Ann. Chim. Appl. [Rome], 6 (1916), No. 9-12, pp. 250-255).—In the examination of gummy substances the results obtained by Fehling's solution were higher than those obtained by the optical procedure (Clerget's formula). During the inversion in the presence of gum appreciable amounts of dextrorotatory material were found to be formed, which caused the discordant results. This was obviated by defecating the sample with basic lead acetate and 95 per cent alcohol. An aliquot from the defecated material is evaporated to remove the alcohol, the residue dissolved in water, and the excess lead removed with alum. The clear filtrate is then treated in the usual manner.

Some analytical data are submitted.

The quantitative determination of minute amounts of sugar by α-naphthol and the estimation of entrainment losses, A. F. BLAKE (Internat. Sugar. Jour., 19 (1917), No. 217, pp. 26-28, fig. 1).—The following procedure is described:

Five cc. of the solution to be tested is placed in a perfectly clean vial and five drops of a 20 per cent solution of  $\alpha$ -naphthol in pure alcohol, together with 10 cc. of concentrated sulphuric acid, are carefully added. The mixture, which becomes very hot, is immediately stirred with a glass rod. In the presence of sugar a purple-red color develops, the intensity being proportionate to the amount of sugar present. After two minutes the color of the solution in the vial is compared with that of a standard prepared in the same manner as the unknown sample.

It is indicated that the error in developing and matching the colors is about 20 per cent. The reaction is not specific, but it is noted that the impurities which might be present do not introduce a great error. The presence of iron interferes somewhat by producing a peculiar coloration.

The test is of special value in determining entrainment losses.

The utilization of cull citrus fruits in Florida, F. A. McDermott, summarized by S. S. Walker (Florida Sta. Bul. 135 (1917), pp. 129-144).—The results of the investigation show that both orange and grapefruit juice can be preserved in the original condition at least for 18 months and probably indefinitely by pasteurization in the absence of air. After proper clarification, the juice may be concentrated by vacuum evaporation to about 20 per cent of its original volume. The concentrated product, flavored with orange extract,

can be packed and preserved in the same way as the fresh juice. The reduction of the juices to a dry material, while possible, is considered hardly to be commercially practicable.

A flavoring oil can be prepared from the peel of the Florida orange by distillation with steam at reduced pressure. The colorless oil so obtained, colored by means of the pigment present in the thin outer peel of the orange, is entirely suitable for marketing. Grapefruit peel was found to contain a similar oil, but in such small amounts that its production would not be profitable.

It is indicated that the juice of decayed fruits, drops, etc., after being sterilized can be fermented for the production of alcohol and the residue used for producing citric acid. The residue from the pulp after the removal of the juice is considered to be suitable for use as stock food. The waste seeds, ground peel, etc., are practically valueless.

The action of ultraviolet rays on the alcoholic fermentation of India fig must, Romolo and Remo de Fazi (Ann. Chim. Appl. [Rome], 6 (1916), No. 9-12, pp. 221-246, figs. 13).—The fermentation of fig must by Saccharomyces opuntice was found to be more vigorous through the action of ultraviolet rays if the time of exposure to the rays was limited. Prolonged exposure caused a gradual diminution of the action of the organism. In the ordinary fermentation of the fig must a heavy film forms on the surface which gradually increases as the fermentation proceeds. No trace of such a film was evident, however, where the fermentation took place under the influence of ultraviolet rays.

Data are submitted in detailed tabular and graphical form and discussed.

The value of supposed household remedies for vinegar disease in wine, W. J. Baragiola and F. Braun (Landw. Jahrb. Schweiz, 30 (1916), No. 5, pp. 509-525).—Data obtained in a study of the value of veal, carrots, and charcoal as remedies for vinegar disease in wine are reported in tabular form and discussed. The authors strongly advise against the use of these materials, as results indicate that they are of no value in curing the disease.

#### METEOROLOGY.

Climatological data for the United States by sections (U. S. Dept. Agr., Weather Bur. Climat. Data, 3 (1916), No. 13, pp. 389, pls. 2, figs. 51).—Summaries and detailed tabulated statements of climatological data for the year 1916 are given for each State.

Meteorological observations, J. S. STEVENS (Maine Sta. Bul. 257 (1916), pp. 357, 358).—A monthly and annual summary of observations at the University of Maine on temperature, precipitation, cloudiness, and wind movement during 1916 is given. The mean temperature for the year was 44.83° F., as compared with an average of 42.77° for 48 years; the total precipitation was 41.2 in., the snowfall 115 in., the number of clear days 213, the number of cloudy days 101, and the total movement of wind 49.818 miles.

Meteorological summary, F. Brown (Wyoming Sta. Rpt. 1916, pp. 95-98).— Monthly summaries are given of observations at Laramie, Wyo., during 1915 on temperature, pressure, precipitation, humidity, sunshine, and wind movement. The highest temperature was 84° F., July 14; the lowest -14°, January 16. The total precipitation was 12.92 in. The highest relative humidity was 100 per cent, January 5; the lowest, 27 per cent, July 12. The greatest velocity of wind was 43 miles per hour, November 19. The first killing frost was October 3.

Relative humidities and vapor pressures over the United States, P. C. DAY (U. S. Mo. Weather Rev., Sup. 6 (1917), pp. 61, pls. 34, figs. 6).—Detailed data are given in tables, charts, and diagrams, and are briefly discussed under the

following heads: Source, amount, and distribution of atmospheric water vapor; influence of atmospheric water vapor on climate; terms "absolute" and "relative" humidity; moist and dry climates; measurements of atmospheric moisture; statistical data available; diurnal changes, annual march, and seasonal variations in relative humidity; absolute humidity; and saturation deficit. Data from recording hair hygrometers for a period of about five years are reported and discussed.

Average rainfall, May and June (U. S. Dept. Agr., Nat. Weather and Crop Bul. 7 (1917), pp. 2, 3, 7, fig. 1).—A chart is given which shows the average rainfall for the period from May 1 to June 30, inclusive, for the 20 years 1895 to 1914. This shows that "the heaviest rainfall during these two months is over the Florida Peninsula, where it reaches between 13 and 14 in. In the lower Mississippi Valley the rainfall is over 10 in. at a number of points, and the chart indicates that there are quite large areas in the Great Plains States where the fall during May and June averages over 9 in., and that this amount is exceeded at a few points in the east-central part of the country. The least rainfall is in southern California and southwestern Arizona, where it is less than 0.5 in. Over most of the region west of the Rocky Mountains the fall averages less than 3 inches.

"In most of the eastern part of the country, except in southern Florida, the annual rainfall is well distributed throughout each month of the twelve. Over the Great Plains region there is much more precipitation during the summer months than falls in winter time. In eastern North Dakota and central South Dakota 80 per cent of the annual precipitation falls during the period from April 1 to September 30, and over a large part of the Great Plains States from western Texas northward to Montana and western Wisconsin, 70 per cent of the annual fall comes between the above-mentioned dates. On the Pacific coast, on the other hand, the rainy season is in the winter time, and very little precipitation occurs from June to October, during most seasons."

A safe method proposed for estimating minimum rainfall, J. P. Wells (Engin. News, 77 (1917), No. 13, pp. 502-504, fig. 1).—The author presents the results of his studies of all the long-time rainfall records of the U. S. Weather Bureau up to 1909 and tabulates the mean, maximum, and minimum annual precipitations. The relations between these records, as calculated, are called maximum-minimum, maximum-mean, and minimum-mean rainfall factors. It is considered essential to have some safe method of determining the minimum rainfall that will occur during a long period of years in order to estimate conservatively minimum run-off conditions. From these studies, it is concluded that the minimum-mean factors afford a safe basis for estimating minimum rainfall.

"In hydraulic investigations it is often the case that only short records of precipitation are available and it is desirable to know what the minimum rainfall for a long period of years would be. If the minimum-mean factor for the locality is known, at least an approximate estimate of the minimum rainfall can be made." The following formula is proposed: " $X=M\frac{(LS)}{L'}$ , in which X=required minimum rainfall, M=minimum-mean factor for the district, L=mean rainfall for entire period at adjacent station which has a long record, L'=mean rainfall at adjacent station during the period in which the records were taken at the station which has a short record, and S=the mean rainfall at the station which has a short record. By averaging the results obtained in the above way from a number of adjacent stations with long records, a safe estimate of the minimum rainfall can be made.

"The results obtained from using the factors 1/2 for 110 years and 2/3 for 50 years are conservative for eastern United States. These factors, however, should not be used for the western part of the country, for they are shown to be much less west of the Mississippi River."

Effect of a late spring upon crop yields (U. S. Dept. Agr., Nat. Weather and Crop Bul. 11 (1917), pp. 2, 3, 5, figs. 4).—Diagrams are given which show the fallacy of the belief that a late spring is usually followed by a poor crop season, especially as applied to corn, oats, and cotton.

Safe dates for planting corn (U. S. Dept. Agr., Nat. Weather and Crop Bul. 8 (1917), pp. 2, 3).—It is stated that the average date of beginning corn planting in the United States varies from February 1 in the extreme South to the latter half of May in the extreme North. The average number of days necessary for maturity of the crop varies from 120 days or slightly less in the North to 150 days or slightly more in the Gulf States. In the corn-belt region the growing period varies from about 130 days in Kansas to 140 days in the Ohio Valley, the period varying, however, with the variety of corn, soil, prevailing temperature, moisture, etc.

"The average date of the first killing frost in the fall east of the Rocky Mountain region varies from about the middle of September in extreme northern districts to December 1 at some distance from the Gulf coast. From Nebraska and Iowa eastward to northern Ohio the first killing frost in the fall is observed on the average between October 1 and 11. From Kansas and Missouri eastward to the Appalachian Mountains the frost date varies between October 11 and 21. In Oklahoma these dates are between October 21 and November 11, while in central and eastern Texas they vary between November 11 and November 25. Eastward across the Southern States from Oklahoma and Texas the variation from the dates recorded in those States is largely a matter of topography. Between the Appalachian Mountains and the Atlantic coast the dates vary from November 1 to 11 in the South; October 21 and November 1 in central districts; and October 11 to 21 farther north. In northern New England and central New York State frost frequently occurs before the middle of September."

The number of days from June 1 to the average first killing frost in the fall varies from 100 to 120 in the extreme North to 120 to 140 in the principal corn-growing region, and from 150 to 170 in the Gulf States.

The above figures show that there are few sections of the country east of the one-hundredth meridian where corn may not safely be planted any time during May, with the expectation that it will mature before the average fall frost date. "In some sections of the central part of the country, and in many districts in the South, corn may be planted until near the close of June, with the expectation that it will mature sufficiently to escape damage from frost nine years out of ten."

Weather and cotton (U. S. Dept. Agr., Nat. Weather and Crop Bul. 9 (1917), p. 3).—From a review of the data bearing on this subject, it is concluded that "in general, the most favorable weather conditions for cotton are warm and comparatively dry weather during May and June and moderate rainfall during the succeeding three months. The most unfavorable are cool and wet weather during the former period and dry and hot during the latter. It is especially harmful for May and June to be cool and wet, as this greatly retards growth and final maturity, and also prevents proper cultivation. For best results thorough cultivation is especially important, owing to the length of the time between the final chopping-out period and the maturity of the last fruit, and the resulting tendency of the fields to become grassy.

"Subnormal rainfall during the months of July and August is more frequently harmful in the western portion of the belt than in the central and eastern portions, owing to the normally greater amounts received in the latter districts. In general, the yield of cotton is largely affected by the rainfall during the months of July and August, especially the latter, but in the central and eastern portions of the belt temperature and moisture conditions during the early period of growth are of scarcely less importance. The amount of rainfall during the latter part of the growing season, particularly in September, is also of special significance, as this largely determines the amount of the top crop, which plays an important part in the total yield."

Safe date for planting potatoes (U. S. Dept. Agr., Nat. Weather and Crop Bul. 10 (1917), p. 3).—It is stated that the potato is "a cool weather crop, and the largest yields in the United States are in the northern tier of States and the Rocky Mountain region, where the mean annual temperature is between 40 and  $50^{\circ}$  and where the July temperature does not average over  $70^{\circ}$  F.

The planting of early potatoes progresses from south to north in the Eastern States in close correlation with the spring temperature of 45°, and is usually nearly one month earlier than the average date of the last killing frost in the spring. The total number of days from planting to harvesting of early potatoes is about 100 in the Central States; 90 in the Southeastern, North Cenral, and Pacific Coast States; and 70 to 90 in the Lake States. The planting of the northern commercial crop becomes general about April 11 in the southern portion of the States running westward from Virginia to Kansas and extreme western Texas, and then extends northward to slightly later than June 1 in extreme northern Ohio, central Michigan, and central Wisconsin.

"Taking the length of the growing period and the first killing frost in the fall into consideration, potatoes should be planted by the first of June in the central and upper Missouri Valley and eastern Rocky Mountain slope, and by June 15 in most districts from the lower Missouri and upper Mississippi Valley eastward to the Atlantic coast in order to thoroughly mature before the average date of killing frost."

## SOILS—FERTILIZERS.

Special crop soils [of New York], E. O. FIPPIN (Cornell Countryman, 14 (1917), No. 7, pp. 568-571, 598, figs. 2).—The so-called general purpose soils of New York, including the light sandy and gravelly soils, heavy clay, and muck soils are discussed.

"The most prominent of these three groups of soil is the muck. . . . Through the central part of the State beds of marl commonly occur under the muck. . . . The smaller and deeper areas of muck are generally the safest for cropping purposes."

Peat moors in the coast regions of southern German East Africa, W. Janensch (Arch. Biontol., 3 (1914), No. 3, pp. 263-276, pls. 2, figs. 2).—This is a report on the origin, formation, and physical and chemical composition of peat moor soils of the Lukuledi and Mbenkuru regions of German East Africa.

Analyses of the ashes and dry substance of samples of the peat from four different localities are reported, showing the potash content to vary from 0.97 to 2.91 per cent in the ash and from 0.22 to 1.3 per cent in the dry matter, the phosphoric acid from 0.41 to 1.34 per cent in the ash and from 0.1 to 0.31 in the dry matter, and the organic matter from 55.24 to 76.91 per cent. The nitrogen content of the organic matter varied from 2.46 to 3.38 per cent. The lime content is considered to be in general relatively lower than that of European peats, being on the average about 9.62 per cent.

Recent studies on nitrification in soils, J. U. SARACHAGA (Bol. Min. Agr. [Argentina], 20 (1916), No. 9-12, pp. 719-728).—This is a review of recent work by the author and others bearing on the subject, in which several different types of organisms were studied.

It is concluded that nitrites are not normally found in a fertile soil, that the reduction of nitrates is always brought about by a certain class of bacteria, and that there are certain conditions of soil favorable to the reduction of nitrates. It was found that none of the organisms examined possesses a nitrifying power comparable to that of the organisms in soil. The total studies appeared to demonstrate that with isolated species only a small amount of nitric or nitrous acid was obtained in solutions.

Fixation of ammonia in soils, I. G. McBeth (U. S. Dept. Agr., Jour. Agr. Research, 9 (1917), No. 5, pp. 141-155, ftg. 1).—Experiments on the fixation of ammonia by soils, conducted in cooperation with the California Citrus substation at Riverside, are reported.

It was found that "many semiarid subsoils have the property of fixing large quantities of ammonia. Much of the ammonia fixed can not be removed by the ordinary methods for determining the ammonia content of the soils. Extracting the soil with 10 per cent hydrochloric acid gives approximately the same quantity of ammonia as distilling the soils with magnesium oxid. Anions apparently have little or no influence on the fixation of ammonia by soils. The ammoniacal nitrogen removed from duplicate samples of soil extracted with 10 per cent acid gives remarkably consistent results, while duplicate samples of soil distilled at atmospheric pressure with magnesium oxid frequently fail to give a satisfactory agreement. A large percentage of the ammonia added to semiarid soils and subsoils can not be recovered by boiling the soil with excessive amounts of caustic solutions. Boiling soils with 10 per cent hydrochloric acid removes practically all of the ammoniacal nitrogen from one soil studied, but less than 75 per cent was recovered from another soil.

"The fixation of ammonia by semiarid soils increases with depth. In this regard semiarid soils appear to differ from humid soils. The addition of ammonum salts in a concentrated solution results in greater fixation than when the same amount is added in a dilute solution. The fixation of ammonia by soils increases with the temperature. The fixation of ammonia by a soil is most rapid during the first few minutes, but the fixation process appears to continue for several days. Heating a soil for six hours at temperatures of 200° C. or above reduces its power of fixing ammonia.

"When small amounts of ammonium salts are added, the percentage of ammonia fixed remains constant. If increasing amounts of ammonia are added, a point is reached at which the percentage fixation becomes less, but the absolute fixation may continue to increase.

"Aluminum, iron, and potassium salts added to soils prior to the addition of ammonia reduce the ammonia-fixing power of the soils very decidedly. Calcium, magnesium, and sodium salts added to the semiarid soils prior to the addition of the ammonia have little effect on the ammonia-fixing power of semi-arid soils. The anions of aluminum, iron, potassium, calcium, sodium, or magnesium salts apparently have no influence on the action of these salts in reducing the ammonia-fixing power of semi-arid soils.

"In semiarid soils the quantity of calcium brought into solution by ammonium chlorid increases with depth; when extracted with aluminum, sodium, or magnesium chlorid, the calcium brought into solution does not increase with the depth."

Relation of the transformation and distribution of soil nitrogen to the nutrition of citrus plants, I. G. McBeth (U. S. Dept. Agr., Jour. Agr. Research,

9 (1917), No. 7, pp. 183-252, figs. 19).—Experiments conducted in cooperation with the California Citrus Substation at Riverside are reported.

It was found that "semiarid soils frequently fail to nitrify dried blood when added in 1 per cent quantities, but invariably nitrify blood when added in amounts not greater than are ordinarily applied under the field conditions. The addition of dried blood to semiarid soils in 1 per cent quantities frequently caused large amounts of ammonia to accumulate in the soil. The addition of dried blood or other nitrogenous substances applied as fertilizers caused no marked increase in the ammonia content of the soils. When 1 per cent of dried blood is added to semiarid soils, as much as 50 per cent of the nitrogen added may be lost during an incubation period of six weeks. As the soils frequently give off a strong ammoniacal odor, it is believed that this loss is due, in a large measure at least, to the volatilization of ammonia. Ammonification or nitrification studies on semiarid soils in which 1 per cent of dried blood is added are of questionable value and may lead to erroneous conclusions.

"Green manures, especially the legume varieties, nitrify very rapidly. As much as 50 per cent of the nitrogen contained in green plant tissues may be converted into nitrates in 30 days. Green manures furnish a valuable source of energy for the nonsymbiotic nitrogen-fixing organisms.

"The furrow system of irrigation frequently causes a very unsatisfactory distribution of the soil nitrates. In many citrus groves more than two-thirds of the nitric nitrogen in the upper 4 ft. of soil is found in the surface 6 in., in which, because of the frequent cultivation, few feeding roots are found. The furrow system of irrigation frequently causes the formation of niter spots. Surface scrapings from these spots in heavily fertilized groves may contain as much as 1 per cent of nitrogen as nitrates. The brown color which characterizes the niter spots is probably due to a number of factors, but it is believed that the deliquescent character of the calcium nitrate is important in this regard. Where the furrow system of irrigation is employed, the fertilizing materials should be plowed down somewhat deeper than the land is cultivated. The feeding roots will then have an opportunity to assimilate the food as it is rendered available, whereas, if it is formed within the cultivated zone, the irrigation will tend to carry it farther away from the roots.

"Much nitric nitrogen is lost from citrus lands by leaching. The most effective means of preventing this loss is by growing a winter cover crop.

"Basin irrigation or overhead irrigation gives a more satisfactory distribution of soil nitrates than the furrow system. The basin system of irrigation seems to give greatest promise when combined with a mulching system. However, the rapidity with which organic materials rich in nitrogen decay would seem to make it inadvisable to maintain a constant mulch with these materials, as the nitrates produced will probably be far in excess of the needs of the tree, and much loss will result."

Conclusions as to mottle-leaf are noted on page -.

Fourteen references to literature bearing on the subject are appended.

Tests on the disinfection of soil, Miège (Compt. Rend. Acad. Sci. [Paris], 164 (1917), No. 9, pp. 362-365).—Two series of experiments on field, garden, and greenhouse soils with potatoes, buckwheat, tomatoes, kidney beans, carrots, leeks, cucumbers, and carnations are reported. The materials used were toluene, carbon bisulphid, lysol, potassium permanganate, copper sulphate, formalin, sulphur, calcium hypochlorite, charcoal, and oxygenated water.

It was found that treatment of the soil with these substances had a favorable influence on the different vegetables on different soils. This favorable influence was found to be specific with reference to the chemical substance used for cer-

tain plants. Thus, in the greenhouse toluene and carbon bisulphid had the best influence on tomatoes. These results are thought to justify the conclusion that the treatment of soils with antiseptics is, on the whole, beneficial.

Chemical studies of the efficiency of legumes as green manures in Hawaii, Alice R. Thompson (Hawaii Sta. Bul. 43 (1917), pp. 26).—The results of the first year's experiments to determine the comparative values for soil improvement of 32 different varieties of legumes on a rich brown calcareous soil from the station grounds and a red, apparently acid, soil low in phosphate and lime from Kunia are reported.

It was found that "the nitrate content of soils in which legumes are growing is low as compared with unplanted check soils, owing possibly to absorption of nitrates by the roots of the growing plants. Where a large amount of leguminous growth is turned under to decompose, the nitrate content of the soil usually is greatly increased.

"Legumes grown on station soil usually showed a higher percentage of nitrogen in the water-free material than those grown on Kunia soil. Liming in a few cases increased the nitrogen content and the nodule development of legumes on Kunia soil. The nitrogen content of the above-ground parts of legumes, although more variable than that of roots, was also usually greater, especially on the station soil, where only the velvet bean and German lupine gave the same value for plant and roots, owing possibly to the large bunches of nodules on their roots. . . .

"In calculations of nitrogen in the entire legume plant on a water-free basis the plants grown on Kunia soil again appear deficient in this element. Liming increased the nitrogen content of the entire plant in case of the jack bean and cowpea, but not of the velvet bean. The crotalarias contained the most nitrogen on both a fresh and water-free basis. As green manure, Sesbania agyptiaca and the velvet bean might be used successfully on Kunia soil if a lime dressing is employed.

"The results of analyses indicate that the nitrogen of leguminous plants is gained through atmospheric assimilation and not from the soil.

"When a legume is to be grown for turning under the roots only, the percentage of nitrogen in the roots and the weight of roots per acre should be considered. The varieties which gave the heaviest yield of root nitrogen per pot were the cowpea, velvet bean, jack bean, Mauritius bean, alfalfa, Indigofera anil, and Phaseolus semierectus grown on station soil.

"From the results obtained in beaker experiments, it appears that one-fifth of the total nitrate nitrogen of cowpeas is converted into soluble ammonia and nitrate salts in three weeks' time. In pot experiments, where the conditions more nearly represented those in the field, in the station soil pots one-half the nitrogen decomposing cowpeas and jack beans was lost through weathering. In Kunia soil a loss of nitrogen was also observed in case of these legumes and also of velvet beans and soy beans, which showed no loss from weathering in station soil, probably because of their later maturity and consequently shorter period of weathering. It appears that in the field, with heavy rains or irrigation, considerable loss of nitrogen probably results through the leaching of soluble ammonia compounds and nitrates from decomposing legumes. It would be advisable, therefore, to follow the turning under of leguminous crops in field soil by the growth of a crop which would utilize the soluble nitrates and ammonia salts formed from the nitrogen of the legumes before they are lost by drainage."

Tests of the value of stable manure, commercial fertilizer, and crimson clover for vegetable crops, T. H. White (Maryland Sta. Bul. 199 (1916), pp. 93-106).—Experiments begun in 1904 to determine the comparative lasting

qualities of stable manure, animal refuse fertilizers, and chemical fertilizers when used on garden crops are reported. The soil was a silt clay loam underlain with yellow clay and was used in five one-fortieth-acre plats.

It was found "that stable manure is cheaper than fertilizer, even at the high price of \$2 per ton. Commercial fertilizers, both of mineral and animal origin, will permanently improve the soil. Such large amounts as 20 tons of manure and a ton and a half of fertilizer were more than could be applied annually with a profit to the crops grown. The residual effects from both the fertilizers and the manure yielded a good profit. The most remarkable gain in the 12 years was in the season of 1915, when 800 lbs. of high-grade fertilizer was applied for tomatoes. This fertilizer, costing \$13.50, made a gain of \$60 per acre."

Experiments begun in 1913 on the use of crimson clover as a green manure for tomatoes on silty clay loam and clay loam soils are also reported. In one experiment crimson clover was plowed under before blossoming and when mature. In the second experiment the clover was cut when in bloom and fed to cattle and the manure returned to the soil and clover was also plowed under when mature.

In the first experiment it was found that on the average the early plowed plat of crimson clover gave the best results. In the second experiment the largest yield was obtained on the plat from which the clover was fed to cattle.

Experiments with nitrogenous fertilizers, I. ÎAKUSHKIN (I. V. JAKOUCHKINE) (Iz Rezul't. Veget. Opytov Lab. Rabot (Rec. Trav. Lab. Agron.), Moskov. Selsk. Khoz. Inst., 10 (1914), pp. 137-144; Izv. Moskov. Selsk. Khoz. Inst. (Ann. Inst. Agron. Moscou), 22 (1916), No. 1, pp. 137-144).—Experiments are reported which showed favorable results from the use not only of ammonium sulphate but also of ground horn and castor bean pomace. Poor results were obtained with fish fertilizer, its effectiveness being only from 40 to 50 per cent of that of sodium nitrate. The nitrogen of manure gave higher results when peat instead of straw was used as litter.

Preparation of dried blood in the army slaughterhouses, A. RANC (Compt. Red. Acad. Agr. France, 3 (1917), No. 15, pp. 428-431).—The quantity of blood which may be collected from the army slaughterhouses for use as a fertilizer is considerable, as the average amount is estimated at 10 kg. (22 lbs.) of blood for each animal. The manufacture of coagulated blood under ordinary conditions is relative simple. A method for collecting the dried blood in the war zone is described in detail. The classical method of preparation of dried blood with the use of ferric sulphate may be used in all the army slaughterhouses, whatever may be their installation. The process is important because of the great quantity of fertilizer which it produces.

The atmospheric nitrogen industry, A. Tobiansky D'Altoff (L'Industrie de l'Azote Atmosphérique. Paris: H. Dunod & E. Pinat, 1914, pp. 16).—This is a discussion of the subject in general and of several processes for the fixation of atmospheric nitrogen in particular.

The displacement of potash by ammonium nitrate, V. N. Zavaritskii (V. N. Zavaritskii (V. N. Zavaritskii) (Iz Rezult. Veget. Opytov Lab. Rabot (Rec. Trav. Lab. Agron.). Moskov. Selsk. Khoz. Inst., 10 (1914), pp. 132–136; Izv. Moskov. Selsk. Khoz. Inst. (Ann. Inst. Agron. Moscou), 22 (1916), No. 1, pp. 132–136).—Ammonium nitrate was found to be more effective than ammonium chlorid in displacing potash from such substances as biotite and similar silicates. The nitrate extracted from biotite appreciable amounts of potash, giving results confirming those obtained in culture experiments in showing that a considerable amount of the potash of this substance is available to plants.

Potash fertilizer salts, D. Van Stolk (Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefstat. [Netherlands], No. 20 (1917), pp. 35-42).—Analyses and tests of 20 per cent potash salts obtained by Holland from Germany after the outbreak of the European war are reported. While consisting principally of sodium and potassium chlorids the 20 per cent salt contained also mixtures of other materials in greater or less quantities. Some samples contained as high as 50 per cent carnallite, others greater quantities of kieserite.

Potash: An investigation into its economic sources in South Australia, D. C. WINTERBOTTOM (So. Aust. Dept. Chem. Bul. 2 (1916), pp. 7-29).—This report deals with the natural potash resources of Australia, including seaweed, ash of land plants, wool scour, sea water, alunite, beet sugar residues, and feldspar. It is concluded that "the sources which present the most promising possibilities seem to be the recovery from wool scouring and the development of the alunite deposits."

Simple tests for potash are described.

Pumping potash from Nebraska lakes, R. P. Crawford (Engin. and Min. Jour., 103 (1917), No. 18, pp. 777, 778, figs. 6).—This is a brief description of the extraction of potash from the brines of Nebraska lakes. An analysis of salts from lake water at Hoffland, Nebr., showed a content of potassium oxid of 27.35 per cent.

Artificial zeolite as a source of potash for plants, A. I. Smenov (Iz Rezul't. Veget. Opytov Lab. Rabot (Rec. Trav. Lab. Agron.), Moskov. Selsk. Khoz. Inst., 10 (1914), pp. 115-131, figs. 2; Izv. Moskov. Selsk. Khoz. Inst. (Ann. Inst. Agron. Moscou), 22 (1916), No. 1, pp. 115-131, figs. 2).—Using the method of "isolated nutrition" described by Prianischnikow (E. S. R., 30, p. 215), it was found that artificial zeolite prepared by the method of Gans but not in contact with other nutritive substances was practically ineffective as a source of potash. When, however, it was mixed with other nutritive salts excellent results were obtained and a nearly normal crop was secured. Slightly better results were obtained with a mixture of phosphorite and zeolite than with zeolite alone in the case of barley, but in the case of buckwheat no advantage from the mixture was observed.

Remarks and technical tests on the preparation of superphosphates, A. AITA (Ann. Chim. Appl. [Rome], 6 (1916), No. 9-10, 11-12, pp. 195-220, figs. 7; abs. in Chem. Abs., 11 (1917), No. 6, p. 682).—Experiments with different rock phosphates, including Florida land pebble, Gafsa, and Constantine phosphates, are reported, the purpose of which was to determine the best conditions for treating phosphorites in order to obtain superphosphates of the greatest solubility and of the best physical state for application to soils. A description of the mechanical and chemical processes involved is given. Tables show analyses of the phosphates, weights of sulphuric acid used, and percentages of soluble and insoluble phosphoric acid obtained.

It was found that for land pebble phosphate from 98 to 100 kg. of acid (53° B.) is required per 100 kg. of the rock meal, for the Gafsa phosphate 86 to 90 kg. of acid, and for Constantine phosphate 96 to 99 kg. of acid of 53 to 54° B. provided the water content of the phosphate does not exceed 4 per cent. Definite results in this respect could not be obtained for other phosphorites.

The water content of the superphosphate is related on one hand to the water content of the mineral phosphate and on the other to the concentration of the acid and degree of heat used during treatment. With acid of 53 to 54° B, a product containing from 13 to 14 per cent of water was obtained with pebble phosphate, and 13 to 15 per cent water with Gafsa and Constantine phosphate. With acid of 52° B, the products contained 15 to 16 per cent water for pebble and 15 to 17 per cent water for Gafsa and Constantine phosphates.

The composition of some Thomas meals, C. J. VAN RAAIJ (Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefstat. [Netherlands], No. 20 (1917), pp. 27-34).—Analyses and tests of samples of Thomas meal imported into Holland after the outbreak of the European war are reported. They are divided into those containing from 7 to 8 per cent of phosphoric acid, considered low-grade, and those containing 15 to 19 per cent. A characteristic of both types of meal was a high content of silica, which is attributed to the addition of sand during manufacture to increase the citrate solubility. The contents of alumina, magnesia, and calcium oxid were somewhat above normal in the low-grade meals and they also contained considerable iron. These constituents were present in normal quantities in the higher-grade meals.

The higher-grade meals are considered to be by-products of processes similar to the Thomas process, and their chemical composition should not interfere appreciably with their agricultural value. The use of low-grade meals, on the other hand, is considered uneconomical, especially on account of their high iron content.

The assimilation of phosphoric acid from phosphorites by cereals, I. V. TAKUSHKIN (Iz Rezul't. Veget. Opytov Lab. Rabot (Rec. Trav. Lab. Agron.), Moskov. Selsk. Khoz. Inst., 10 (1914), pp. 66-84, figs. 6; Izv. Moskov. Selsk. Khoz. Inst. (Ann. Inst. Agron. Moscou), 22 (1916), No. 1, pp. 66-84, figs. 6).—Tests of certain Russian phosphorites on wheat in sand cultures showed that these phosphorites were from 60 to 70 per cent as effective as superphosphate. From 10 to 15 per cent of the phosphoric acid was soluble in alkaline ammonium citrate which dissolves only traces of phosphoric acid from ordinary phosphorites.

The assimilation of phosphoric acid of phosporite by plants under different conditions of nutrition, F. V. Chirikov (T. V. Tchirikov) (Iz. Rezul't. Veget. Opytov Lab. Rabot (Rec. Trav. Lab. Agron.), Moskov. Selsk. Khoz. Inst., 10 (1914), pp. 149–171, figs. 4; Izv. Moskov. Selsk. Khoz. Inst. (Ann. Inst. Agron. Moscou), 22 (1916), No. 1, pp. 149–171, figs. 4).—Experiments are reported which showed that Spergula arvensis, Trifolium resupinatum, Vicia faba, and Onobrychis sativa grown with phosphorite contained appreciable amounts of phosphoric acid, while Andropogon sorghum, Panicum germanicum, Zea mays, and Camelina sativa showed little power of assimilation of phosphorite. The yields of cereals were greater with small amounts of lime in solution than with large. The plants which utilized the phosphorites best appeared least sensitive to changes in the composition of the nutritive solution.

The value of diphosphate, I. V. ÎAKUSHKIN (J. V. JAKOUCHKINE) (Iz Rezul't. Veget. Opytov Lab. Rabot (Rec. Trav. Lab. Agron.), Moskov. Selsk. Khoz. Inst., 10 (1914), pp. 51-65, figs. 6; Izv. Moskov. Selsk. Khoz. Inst. (Ann. Inst. Agron. Moscou), 22 (1916), No. 1, pp. 51-65, figs. 6).—It is pointed out that the phosphoric acid of precipitated phosphate (disphosphate) is much more soluble in water than that of Thomas slag. Experiments are reported which show that on the rich black soils of southern Russia the precipitated phosphate is equal, and in some cases superior, to superphosphate for millet and sugar beets.

Causes influencing the solubility of difficultly soluble phosphates in citric acid, A. AITA (Ann. Chim. Appl. [Rome], 6 (1916), No. 3-4, pp. 119-131, fig. 1).—Continuing studies previously reported (E. S. R., 36, p. 626), experiments on the influence of salts of manganese, iron, aluminum, and magnesium in mineral phosphates and phosphatic slags on the solubility of the phosphoric acid therein are reported.

It was found that the secondary constituents of phosphatic slag may be divided into two groups, (1) those which interfere with the solubility in citric

acid of the phosphoric acid, such as lime, silicates, and manganese, and (2) those which favorably influence the solubility of the phosphoric acid, such as the sulphates of aluminum and iron. It is thought that the salts of iron and aluminum when present act in neutralizing the effect of those compounds which retard the solubility.

It is concluded that phosphatic slags contain tricalcium phosphate the same as do mineral phosphates, and that their high degree of solubility in citric acid may be attributed to the specific action of the iron and aluminum ions present as secondary constituents. It is further concluded that variations in the solubility of phosphatic slag are due to variations in the content of the secondary constituents.

The influence of calcium carbonate on the solution of iron phosphate in acetic acid and its availability to plants, V. V. Semushkin (Semouchkine) (Iz Rezul't. Veget. Opytov Lab. Rabot (Rec. Trav. Lab. Agron.), Moskov. Selsk. Khoz. Inst., 10 (1914), pp. 85-103; Izv. Moskov. Selsk. Khoz. Inst. (Ann. Inst. Agron. Moscou). 22 (1916), No. 1, pp. 85-103).—The addition of calcium carbonate to iron phosphate was found to reduce its solubility in acetic acid and to reduce its effectiveness as a food for plants grown in pots. Calcium nitrate produced no such effect on the solubility in acetic acid but produced analogous effects in pot experiments. Magnesium carbonate acted like calcium carbonate but to a less degree. Sodium carbonate increased the solubility of the phosphoric acid. The effect of ammonium nitrate varied at different periods of growth. The addition of calcium carbonate in this case increased growth during the first period and gave a larger yield.

Analyses of inspection samples of fertilizers, 1915-16, J. T. WILLARD and R. C. WILLY (Kansas Sta. Insp. Circ. 3 (1916), pp. 17).—This circular contains the results of actual and guarantied analyses of 76 samples of fertilizers and fertilizing materials collected for inspection in Kansas during 1915-16, together with financial statements relating to such work and the text of the Kansas fertilizer law.

Analyses of inspection samples of fertilizers, fall 1916, J. T. WILLARD and R. C. WILEY (Kansas Sta. Insp. Circ. 4 (1917), pp. 11).—This circular contains the results of actual and guarantied analyses of 57 samples of fertilizers and fertilizing materials collected for inspection in Kansas during the fall of 1916, together with a list of Kansas fertilizer dealers.

Fertilizers sold in Wisconsin, W. H. Strowd (Wisconsin Sta. Bul. 279 (1917), pp. 13, fig. 1).—This bulletin gives general information on the purchase and use of commercial and other fertilizers and fertilizing materials, with special reference to Wisconsin conditions, and reports the results of actual and guarantied analyses of 49 samples of fertilizers and fertilizing materials collected for inspection in the State during 1916. It is stated that in Wisconsin most of the commercial fertilizers are used in sections where truck and cash crops predominate, the largest amounts being used in Milwaukee, Racine, and Kenosha Counties in the extreme southeastern part.

#### AGRICULTURAL BOTANY.

A quantitative method of ascertaining the mechanism of growth and of inhibition of growth of dormant buds, J. Loeb (Science, n. ser., 45 (1917), No. 1166, pp. 436-439).—Studies are reported on the development of the dormant buds in the leaves of Bryophyllum calycinum.

Leaves of equal size and from the same node were found to produce, in the same time and under identical conditions, equal masses of young shoots. From experiments with two sets of leaves, one with the centers cut out, the other

intact, it was found that the production of shoots is in proportion to the mass of the leaves themselves. The investigation here reported leads to the assumption that the growth of dormant buds is determined by and is in proportion to the quantity of a certain material available for the buds. The author does not discuss the nature of the substances which cause the growth of buds, but he points out the fact that leaves form no shoots or very few if kept in the dark. This is believed to indicate that the material from which the new shoots are produced in a leaf is itself to a large extent a direct product of or is dependent upon the assimilatory activity of the leaf.

Influence of the leaf upon root formation and geotropic curvature in the stem of Bryophyllum calycinum and the possibility of a hormone theory of these processes, J. Loeb (Bot. Gaz., 63 (1917), No. 1, pp. 25-50, figs. 30).—In studies previously noted (E. S. R., 37, p. 127), which showed that substances (water or solutes) may be drawn away from the leaves to accelerate organ formation in the stem but that if not so removed, they will accelerate root and shoot growth in the leaf notches, it was observed also that the leaf has an accelerating influence upon the geotropic curvature of the stem itself. The present article notes a number of studies by the author on the influence in this connection of such factors as the presence, absence, or position of leaves; splitting, decortication, or notching of the stem; and combinations of these factors on the degree of geotropic bending.

It appears that in *B. calycinum*, the substances which induce root formation tend to collect on the lower side of a stem placed horizontally, although roots may appear also in notches on the upper side under conditions to be discussed in a later paper. Leafless stems curve and form roots much more slowly than do those having one or more leaves. The position and number of the leaves influence in certain ways the geotropic curvature. Generally it appears that each leaf sends shoot-forming substances toward the apex and root-forming substances toward the base of the stem. The probable significance of these and other observed facts is discussed.

The spontaneous negative geotropism of roots, Eva Mameli and Eligia Cattaneo (Separate from Atti Ist. Bot. R. Univ. Pavia, 2. ser., 17 [1916], pp. 12).—Concluding a study of negative geotropism and related phenomena observable in Helianthus annuus and in some other plants, the authors state that in spontaneous negative geotropism the root cap becomes shorter and more obtuse than in case of roots positively geotropic. It presents an evident arrest of development with complete absence of starch in that portion during that stage, although starch appears in the stage immediately preceding a new orientation of the rootlet consequent upon the development of diageotropism or positive geotropism. In such case the starch is always found in the physically inferior part of the cell.

The behavior of certain gels useful in the interpretation of the action of plants, D. T. MacDougal and H. A. Spoehe (Science, n. ser., 45 (1917), No. 1168, pp. 484-488).—The authors claim that the systematic endeavor to construct a colloidal mixture which would display some of the fundamental physical properties of protoplasm of plants has resulted in finding that a mixture of substances of two of the three more important groups of constituents, carbohydrates, and proteins, shows the imbibitional behavior of tissues and tracts of protoplasts of the plant. The differential action of such colloidal masses in distilled water and acid and alkaline solutions is said to yield many striking parallels with growth.

The effect of continuously supplying water to plants by capillarity, L. Daniel (Compt. Rend. Acad. Sci. [Paris], 163 (1916), No. 19, pp. 525-527).—Several garden plants supplied with water permitted to percolate continuously,

but very slowly as evaporated by the plant, through cotton or wool to the roots, were found to utilize water much better and more economically than did plants watered in the ordinary way. They also showed modifications as to growth and qualities which suggest the profitable employment of apparatus by which a known quantity of water can be furnished as the needs of the plant may require.

A study of permeability by the method of tissue tension, S. C. Brooks (Amer. Jour. Bot., 3 (1916). No. 10, pp. 562-570, figs. 3).—It is claimed that the permeability of the protoplasm of Taraxacum officinale remains practically normal in a balanced mixture consisting of sea water and calcium chlorid, such that the ratio of univalent to bivalent cations is about 70:15. Salts of univalent cations cause a great increase, those of bivalent or trivalent cations a great decrease, in permeability. Saccharose permeates protoplasm rapidly, affecting permeability as a univalent cation.

Similarity in the effects of potassium cyanid and of ether, W. J. V. OSTER-HOUT (Bot. Gaz., 63 (1917), No. 1, pp. 77-80, fig. 1).—As relating to the evidence obtained by the author (E. S. R., 28, p. 732) that typical anesthetics temporarily decrease permeability, instead of increasing it as claimed by Krehan (E. S. R., 34, p. 333), the author has carried out experiments on the permeability of the tissues of Laminaria agardhii. This was measured by determining electrical resistance in the manner described in an article previously noted (E. S. R., 26, p. 823), in order to ascertain the manner in which permeability is affected by potassium cyanid, which not only acts as an anesthetic but markedly inhibits oxidation.

In tissue placed in sea water to which had been added potassium cyanid so as to give molecular concentrations ranging from 0.002 to 0.381 no such temporary increase of permeability was observed as described by Krehan. Experiments demonstrated that there is a temporary decrease of permeability instead of a temporary increase. Whenever the permeability began to increase, it continued to increase steadily until the tissue was dead.

The fact that potassium cyanid resembles typical anesthetics such as ether and chloroform in producing a temporary decrease in permeability does not, in the opinion of the author, show that anesthesia is a form of asphyxiation. It is considered probable that the decrease of permeability and the anesthesia produced by potassium cyanid are related to its effect on oxidation.

The mode of action of the oxidases, H. H. Bunzel (Jour. Biol. Chem., 24 (1916), No. 2, pp. 91-102).—The results of studies by the author on the oxidase activity (this term being preferred, for reasons stated, to concentrations of oxidases) in different portions of various plants are presented and discussed. They are considered to show that in the work under discussion several factors were operative, each exerting either an augmenting or a depressing effect on the end result. The presence of reductases and the concentration of hydrogen ions are thought to affect the results, but the nature of their action is not yet clear.

The relative oxidase activity of different organs of the same plant, H. H. Bunzel (Jour. Biol. Chem., 24 (1916), No. 2, pp. 103-110, figs. 5; abs. in Jour. Chem. Soc. [London], 109 (1916), No. 643, I, p. 357).—The author has used in this work the oxidase unit as employed in that previously noted (E. S. R., 27, p. 9) and defined in this article as an oxidase solution of such strength that 1 liter will bring about the consumption by pyrogallol of 8 gm. of oxygen, or the equivalent of 1 gm. of hydrogen.

The results, as shown in tabular and graphical form, of experiments with potato leaves and tubers, onion leaves and bulbs, tulip tree leaves and buds, and spinach leaves and roots, show a marked parallelism between the oxidase

activities of different parts in the potato, tulip tree, and sugar beet. The onion showed no oxidase activity in either leaves or roots, and the graphs for these parts in spinach were entirely at variance, so far as appearances indicate. Each plant apparently has its characteristic relationships.

The results of this work are considered to indicate that the capacity of the plant to oxidize the various compounds employed is characteristic of the particular plant, but that it varies in intensity, and in this respect only, in the different parts of the same plant, showing a distinct and characteristic type of metabolism for each plant. It remains to be investigated to what extent plants of the same genus or species resemble each other in their metabolism.

A comparative study of winter and summer leaves of various herbs, J. P. Stober (Bot. Gaz., 63 (1917), No. 2, pp. 89-109).—Summarizing the findings and conclusions of a study carried out with numerous plants collected near Chicago or in eastern Pennsylvania, the author states that typical rosette leaves in shaded and protected situations are on the whole decidedly more mesophytic than are stem leaves, which are exceeded as regards xerophytism by winter leaves on stolons or runners.

Local and temporary autumnal symbiosis, L. Montemartini (Separate from Atti Ist. Bot. R. Univ. Pavia, 2. ser., 17 [1916], pp. 7).—The author, having observed cases in which the portions of leaves of Acer platanoides which were parasitized by Uncinula aceris remained green while other parts went through the regular autumnal changes, and cases of similar behavior in Corylus avellana attacked by Phyllactinia suffulta, has made a study of maple leaves during a period nearly coincident with the first half of November.

It was found that the dry matter of the leaf was greater in the parasitized areas than outside them during this period, especially during the middle portion. The ratio of ash content to dry substances was somewhat less during that period in both green and yellow portions of the leaves. From these and other facts it is concluded that these cases may represent a temporary symbiosis, due to a diminution of virulence of the parasite and to a variation in the resistance of the host during this period owing to the effects of external conditions then prevalent.

The penetration of foreign substances introduced into trees, W. H. RANKIN (*Phytopathology*, 7 (1917), No. 1, pp. 5-13, fig. 1).—Experiments are reported upon in which chestnut trees from 2.5 to 9 in. in diameter were fed solutions of lithium nitrate, a modification of the Shevyrev method being employed (E. S. R., 15, p. 60).

An examination of cross sections of the trunks of the trees showed that lithium nitrate, under the method employed, penetrates to all places in the tree where there is active translocation of food materials; that is, to all parts of the bark and sapwood above and below the point of feeding. Complete penetration of the heartwood was obtained in trees of less than 3 in. in diameter. In trees of greater diameter the process of penetration was slow and did not seemingly follow any definite rule.

The injurious effects of tarvia fumes on vegetation, A. H. CHIVERS (*Phytopathology*, 7 (1917), No. 1, pp. 32-36).—Following up observations of the effect of tarvia fumes on growing plants where at least 20 species and many varieties were injuriously affected (E. S. R., 35, p. 734), the author presents data secured from laboratory investigations which confirm the previous conclusions.

Experiments conducted under controlled conditions showed that the injury was due in large part to the volatile substances, which condensed in the form of an oily coating on the surfaces of the plants. The injury is considered due to the action of fumes on the aerial parts of plants, its amount varying

with the distance from the escaping fumes, the temperature of the melting tar, the age of the plant structures, and the species used.

Imperfection of pollen and mutability in the genus Rosa, RUTH D. COLE (Bot. Gaz., 63 (1917), No. 2, pp. 110-123, pls. 3).—A study of all obtainable species of Rosa carried out by the author during the winter of 1915-16 is said to have shown that these species are characterized by great variability and by a large proportion of abortive pollen. From this it is inferred that these species are largely of hybrid origin, due to contamination in nature, and hence that the mutability of the species of this genus can not properly be used in support of the mutation hypothesis.

Enothera lamarckiana velutina, H. de Vries (Bot. Gaz., 63 (1917), No. 1, pp. 1-24, pl. 1).—Observations during several years of cultures from Enothera mutations having tended to show that such mutation phenomena are far more complex than they were formerly assumed to be, the author is now giving attention to the question whether the characters of Enothera mutants and hybrids are single or built up of a greater or less number of theoretically independent units. E. lamarckiana velutina has been chosen for this work on account of its alleged freedom from specific admixtures. A number of crosses were made in 1915, but this article gives chiefly a description of the mutant itself and of those hybridizations which give proof of its right to the name it bears.

A study of this new mutant shows the existence of at least two recessive characters in Œ. lamarckiana, namely, the bubbles of the leaf blade and the presence of typical empty seeds.

The cowhage and related species, C. V. PIPER (Proc. Biol. Soc. Wash., 30 (1917), pp. 51-62).—In connection with investigations of the Florida velvet bean and other cultivated forms of velvet bean, the author has made a study of various related species characterized by having stinging hairs on the calyx and pods. The species of Stizolobium which are distinguished from Mucuna by well defined characteristics are grouped under two subgenera. The name for the well-known stinging-haired species should be S. pruriens. S. pruritum is described as a new combination with several varieties, and S. microspermum, S. venulosum, and S. forbesii are described as new species. S. hirsutum is the name given for the species formerly known as M. hirsuta.

## FIELD CROPS.

Dry farming in eastern New Mexico, J. E. Mundell and H. G. Smith (New Mexico Sta. Bul. 104 (1917), pp. 61, figs. 15).—This is a popular discussion of general crop conditions and methods of farming in the dry-land area of eastern New Mexico for the purpose of furnishing information to present and prospective settlers. The information is based upon extensive observations of dry-farming methods in eastern New Mexico and other dry-farming districts and on results obtained in experiments conducted by the Office of Dry Land Agriculture, of the U. S. Department of Agriculture, at the dry-land field station, Tucumcari, N. Mex.

In addition to a discussion of the general factors to be considered in dryland agriculture, such as the limiting factors encountered, the cultural practices employed, the most suitable crops, etc., considerable crop and climatological data secured at the field station are presented and discussed. The average annual precipitation at Tucumcari for a 12-year period was 16.21 in., over 70 per cent of which fell between April 1 and October 1. The average evaporation from a free water surface for the 4-year period 1913 to 1916, inclusive, was 54.003 in, for the 6-month period from April 1 to October 1. The total evaporation varied from 49.92 in. in 1914 to 58.901 in. in 1916.

The crop data show the yields per acre of milo maize, Kafir corn, sorgho, broom corn, Sudan grass, millet, cowpeas, beans, cotton, corn, winter wheat, winter rye, spring wheat, oats, and barley under various cultural conditions. From the results obtained it has been concluded that summer fallowing and subsoiling are relatively unprofitable, while fall and spring plowing and listing are deemed to be the methods best adapted for use in preparing the land.

Tests with sorghum planted in rows 8, 16, 24, 32, and 44 in. part, respectively, conducted during 1914, 1915, and 1916 gave the highest yields with planting widths of 24, 32, and 44 in.

Date-of-planting tests with Mexican June corn gave the best results with plantings between May 1 and June 10. Tests with Dwarf Milo gave the best results with plantings made between May 10 and June 10.

Tabulated data are presented showing the effect of the previous crop on the yields of the several crops listed above, obtained on land cropped continuously and on land where systematic rotation has been practiced.

Variety tests begun in 1912 are reported for grain sorghums, forage sorghums, millets, cowpeas ,broom corn, beans, cotton, corn, peanuts, and potatoes.

Progress report of Substation No. 3, Angleton, Tex., 1909–1914, N. E. Winters (*Texas Sta. Bul. 197 (1916*), pp. 3-20, figs. 4).—Varietal, rotation, and cultural tests with corn, cowpeas, and oats, and field tests with leguminous forage crops, sorghum for forage, Japanese sugar cane, Sudan grass, and dasheens are reported for the seasons of 1913 and 1914.

The Strawberry, Thomas, and Chisholm corn varieties gave the highest yields based on a 2-year average, 27.78, 27.3, and 26.21 bu. per acre, respectively. The lowest-yielding variety was Collier Excelsior, with 18.24 bu. The highest average yield, 18.36 bu., in seeding-rate tests was secured from rows 3 ft. apart, with the stalks 2 ft. apart in the row, giving 7,260 plants per acre. Different row widths, with various distributions of the plants in the row, showed practically no variation in yields so long as the total stand remained constant. On sowing cowpeas in 1913 between the corn rows when the corn was beginning to tassel, a yield of 20.32 bu. of corn was obtained, as compared with a yield of 17.1 bu. in 1914 from corn grown alone. A comparison of planting dates for the cowpeas indicated that plantings made with the corn in full tassel gave increased yields of corn over earlier plantings. A rotation of cotton, cowpeas for seed, corn, and oats, with cowpeas plowed under as a green manure, showed increased corn yields of 2.27 bu. in 1913 and 9.94 bu. in 1914 over corn grown continuously.

Oats were grown for hay only, Rust Proof, with a yield of 968 lbs., and Appler, with 836 lbs. of cured hay per acre, giving the best results. Frazier Red Rust Proof gave the lowest yield, 678 lbs., while Virginia Gray Winter failed entirely, due to rust. The quality of 100-Bushel Oats was superior to that of all other varieties, the yield being 682 lbs. of hay. Oats grown in rotation in 1914 produced 1,235 lbs. of cured hay per acre, while only 528 lbs. was secured from oats grown continuously.

Based on a 2-year average yield of cowpeas for seed and forage, New Era with 18.89 bu., Whippoorwill with 17 bu., and Groit with 14.88 bu. per acre, gave the highest yields of seed, with Blackeye lowest with only 2.77 bu. For hay production the Iron variety was first, with a yield of 2,571 lbs. of cured hay per acre, Groit second with a yield of 2,270 lbs., and Red Ripper lowest with 1,210 lbs. Seeding rates of 6, 12, and 18 lbs. per acre for hay production in 1913 showed yields of 2,640, 3,300, and 3,685 lbs. of cured hay, respectively. The results obtained with cowpeas grown in rotation, as compared with con-

tinuous cropping, show very little difference both in yield of grain and forage for 1913 and 1914.

In seeding-rate tests with sorghum for forage, the highest average yield, 16,742 lbs. per acre, was secured from a seeding rate of 8 pk. per acre in close drills, but a 2 pk. rate gave an average yield of 16,740 lbs. Plants sown in 3-ft. rows, 1 in. apart in the row, and cultivated, gave an average yield of 16,026 lbs., the highest for seedings in cultivated rows.

Harvests of Japanese sugar cane secured September 10, December 4, and December 16, 1914, yielded 23,200, 51,030, and 39,820 lbs. of green forage per acre, respectively.

Method-of-seeding tests with Sudan grass showed average yields of 4,266, 6,124, and 5,302 lbs. of cured hay per acre for seedings in 3-ft. rows, 18-in. rows, and close drills, respectively. Sudan grass is considered valuable chiefly as a summer grazing crop, as sorghum is preferred for hay in this section and Japanese sugar cane gives higher yields of green forage than either sorghum or Sudan grass. Sudan grass does not produce seed on account of the prevalence of the sorghum midge.

Dasheens are reported as giving promise for the future.

Progress report, Texas Substation No. 6, Denton, Tex., 1909-1914, V. L. Cory (Texas Sta. Bul. 199 (1916), pp. 3-18, figs. 3).—Variety tests with wheat, barley, oats, rye, corn, cowpeas, and peanuts, and cultural and field tests with wheat, emmer, spelt, cotton, miscellaneous legumes, and Sudan grass, are reported for the crop years 1910-1914, inclusive.

Twenty-one winter wheat varieties have been tested, including 8 hard red, 7 soft bearded, and 6 soft beardless varieties. Defiance and Bacska, with 3-year average yields of 27.04 and 24.93 bu. per acre, respectively, were the leading hard red wheats. The durum and spring wheats have not proved of much value.

Eight varieties of winter barley and 6 of spring barley were tested. A comparison of the average yields of 4 varieties grown both as winter and spring varieties in 1912 and 1913, showed a decreased yield of 6.08 bu. per acre from spring seeding. The highest-yielding winter variety was White Smyrna, with 32.65 bu., and the lowest, Hooded barley, with 11.21 bu. These two varieties also gave the highest and lowest yields when grown as spring varieties, with yields of 18.22 and 12.03 bu., respectively.

Red Rust Proof oats is the standard variety for the section, both for fall and spring planting. Sixty-Day, Burt, and Ninety-Day are deemed excellent varieties for late seeding and for dry seasons. No appreciable advantage has been gained by fall seeding as compared with spring seeding.

Comparative tests of Tennessee Winter barley, Red Rust Proof oats, Red Winter spelt, and Black Winter emmer for 1912, 1913, and 1914 have shown average yields of grain of 1,541, 1,355, 1,074, and 887 lbs. per acre, respectively.

Three rye varieties were tested and gave practically identical results. Rye is not considered of great value for this region.

A comparison of early and late plowing and of deep and shallow plowing of stubble land for wheat showed yields of 32.62 bu. for deep, early plowing as compared with 20.41 bu. for shallow, late plowing. Cultivation of the soil after plowing the wheat was followed by a yield of 32.62 bu. as compared with 17.41 bu. from land not cultivated. Corn land plowed in preparation for wheat yielded 28.08 bu. per acre with wheat drilled in and 25.5 bu. with wheat broadcasted. Disking and drilling in the wheat gave 25.25 bu., broadcasting 20 bu., and drilling wheat in without any preparation 18.66 bu.

In corn variety tests Surcropper has given the best results, with June corns good varieties for late seeding.

The Early Buff variety of cowpea has given the highest yields of seed, with New Era, Blackeye, Iron, and Brabham also reported as satisfactory.

Spanish, Virginia, and Tennessee Red peanuts yielded an average of 476, 460, and 105 lbs. of seed, and 3,890, 4,350, and 850 lbs. of hay, respectively.

None of the legumes tested has proved especially well suited to local conditions.

Tests with Sudan grass for forage showed a total yield of 4,575 lbs. per acre when sown April 30 in 36-in. rows. Sudan grass is considered a valuable hay and pasture grass for this section.

Progress report of Substation No. 12, Chillicothe, Tex., 1905–1914, R. W. Edwards (Texas Sta. Bul. 202 (1916), pp. 3-30, figs. 13).—Forage-crop work conducted in cooperation with the Office of Forage Crop Investigations, U. S. Department of Agriculture, is reported for the 10-year period of 1905 to 1914. The field experiments include variety and date- and rate-of-planting tests with sorghums, date-, rate-, and method-of-seeding tests with Sudan grass for hay, and variety tests with alfalfa.

Meteorological data for 1906–1914 show a mean annual rainfall of 25.03 in. The maximum annual precipitation was 32.47 in. in 1908, and the minimum 14.19 in. in 1910.

Kafirs have outyielded milos in both forage and grain in favorable seasons, but in poor growing seasons milo maize and feterita were both more productive than Kafir corn. The latter yielded 2.1 tons of forage and 10.3 bu. of grain as compared with 1.68 tons of forage and 15 bu. of grain for milo maize for an 8-year average, 1907–1914. Drought resistance in Kafir corn was evidently secured at a sacrifice in yield in good seasons, since the most drought-resistant strains did not respond to abundant moisture in the same proportion as did many of the common or standard varieties.

Selection F. C. I. No. 811 of dwarf feterita proved earlier, more dwarf and uniform in height, and produced higher yields at Chillicothe than the original S. P. I. No. 19517. Kaoliang proved to be of relatively little importance for this region.

Amber (saccharin) sorghums were early maturing and produced a good quality of hay when sown broadcast or in close drills. Sumac or red top sorghums gave larger yields than the ambers, but, unless planted thickly, produced rather coarse hay. Honey and gooseneck sorghums proved suitable for sirup making and for silage, but produced inferior hay.

The grain sorghums have produced the best yields of grain and forage when planted from April 15 to May 15 for seed, and from June 15 to July 1 for forage, with the plants from 4 to 8 in. apart in the row. The sorghums have produced the best quality and quantity of forage with plants from 2 to 4 in. apart in the row. Seedings of 75 lbs. per acre for sumac and 45 lbs. for red amber in close drills have given the best hay yields.

Sudan grass seeded at the rate of 15 lbs. per acre in close drills produced 1.51 tons of hay per acre in 1913 and 5.57 tons in 1914. Medium early plantings, April 3 to May 4, gave the largest number of cuttings, and an average yield of about 5.19 tons in 1914. About the same yields but a better quality of hay was secured from seedings in close drills over those in cultivated rows. Considerably more seed was produced in cultivated rows than in drilled plats.

Of the millets tested Turkestan was the highest yielder and produced a good quality of hay. The millets are considered inferior to Sudan grass for hay purposes.

Early Buff, Brabham, Iron, Groit, New Era, and Red Ripper are all considered excellent cowpea varieties, especially suited for use as annual leguminous

crops for rotations. Chiquita, Mammoth, Cloud, and Jet for forage, and Haberlandt for seed production, proved to be good soy-bean varieties. All soy beans suffered from rabbit depredations.

Kansas, Wyoming, and Algeria alfalfas have produced good yields. A comparison of close drilling with cultivated rows 42 in apart gave a yield of 2.25 tons per acre for the former method and 1.31 tons for the latter in 1914. Artificial inoculation is not recommended for this region.

About 50 varieties of vetches were tested, but none proved suitable for the locality.

Sunflowers have been tested extensively but were not considered profitable, due to their susceptibility to insect attack.

Inheritance in wheat, barley, and oat hybrids, E. F. GAINES (Washington Sta. Bul. 135 (1917), pp. 3-61, figs. 9).—Extensive hybridization studies are reported with 6 wheat, 7 barley, and 9 oat varieties, the standard commercial varieties of Washington being used wherever the proper combinations could be obtained.

The following characters were studied: Wheat—beards v. no beards, long head v. club head, and white grain v. red grain; barley—beards v. hoods, bald v. covered grain, 6-row v. 2-row heads, and winter v. spring types; and oats—white v. black grain color, side v. tree type of panicle, and hulled v. hull-less character. The results of the hybridization are discussed in detail and considerable tabulated data presented, showing the hybrid composition and relative frequency of the characters studied in the  $F_1$  and  $F_2$  generations.

While many of the observations recorded are corroborative of work published in America and Europe, other results were secured which are briefly summarized below.

The following characters segregated as simple allelomorphs in the  $F_2$  generation: Beardless wheat was dominant over bearded, and club head over long head; hooded barley was dominant over bearded, covered over bald, and 2-row over 6-row; and black oats were dominant over white. The remaining characters were produced by multiple factors, or were irregular in inheritance.

In the bearded and beardless wheat hybrids, the  $F_1$  was intermediate and could be segregated in the  $F_2$ . The heterozygote of the bearded and hooded barley crosses could not be so segregated, and large numbers carried into the  $F_0$  failed to produce modified types of these characters.

Two different crosses of spring barleys produced winter plants in the ratio of 3:13 in the  $F_2$  generation.

One variety of white hulless oats produced black oats when crossed with white hulled varieties. Hullessness prevented the development of glume color in the parent and hybrids of all the crosses tested. Crosses of side and tree oats produced intermediate types which bred true in subsequent generations. The percentage of hulled plants in the F<sub>2</sub> of crosses between hulled and hulless oats approached a simple Mendelian recessive, but there was great irregularity between the true hulless and heterozygous types, with an excess of heterozygotes in most cases.

Winter oats, barley, spelt, and emmer, N. Schmitz (Maryland Sta. Bul. 200 (1917), pp. 107-130, figs. 8).—Variety tests with winter oats, winter barley, spelt, and emmer since 1907 are reported and the production of the crops discussed.

Dewey, Bicknell, and Culberson, with average yields of 51.23, 49.89, and 49.49 bu., respectively, for the period of 1908–1914, inclusive, were the leading out varieties tested. The lowest-yielding variety was Boswell, with 22.66 bu. Further data show the percentage of winterkilling, average date of ripening, and average height of plants for the varieties tested. In extensive tests over

the State, Culberson and Winter Turf proved a little more hardy than Bicknell and were also better adapted to light, sandy soils of medium to poor fertility and are considered best for Maryland conditions. The Culberson, Bicknell, Winter Turf, Dewey, and Red Rust Proof varieties are briefly described.

The two leading barley varieties were Mammoth Winter, with an average yield of 34.64 bu., and Maryland Winter, with 34.59 bu. Tennessee Winter, yielding 30.43 bu., is recommended together with the two varieties named above because of its ready availability on the market.

Five varieties of spelt and 3 of emmer were tested. Alstroum spelt yielded an average of 63.23 bu., but contained 40 per cent hulls to grain. Black Winter emmer yielded 34.43 bu.

The total weight of grain produced per acre of the highest yielding variety of wheat, oats, barley, spelt, and emmer was as follows: Bearded Purple Straw wheat 2,412.2 lbs., Dewey oats 1,639.4 lbs., Mammoth Winter barley 1,662.5 lbs., Alstronum spelt 1,896.9 lbs., and Black Winter emmer 1,032.9 lbs.

Grains for the dry lands of central Oregon, L. R. BREITHAUPT (U. S. Dept. Agr. Farmers' Bul. 800 (1917), pp. 2-22, figs. 6).—The production of small grains on the nonirrigated lands of central and southeastern Oregon at elevations of from 4,000 to 5,000 ft. is discussed. The information presented is based partly upon the results of three years' experiments conducted in cooperation with the Oregon Experiment Station, at the Harney substation at Burns, and applies only where the rainfall, summer frost, and winter cold are average and where the nature, depth, and alkali content of the soil are favorable for crop production.

The important cereal crops for the region as a whole are winter and spring wheat, winter and spring rye, spring oats, and spring barley. Flax, field peas, and dry-land alfalfa are important but are not yet fully established. Minor crops include emmer, spelt, rape, sweet clover, root crops, and potatoes. Crops which have proved to be rather definitely unadapted to the average conditions are corn, millet, sorghum, beans, buckwheat, and cultivated grasses.

Grasses used in binding the shifting sands of southern Italy, A. Borzi (Bol. R. Giard. Colon. Palermo, 2 (1916), No. 4, pp. 189-213, figs. 6; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 5, pp. 646, 647).—The problems encountered in finding suitable grasses to bind the shifting sands of southern Italy are reviewed, and Saccharum spontaneum described in detail and its value for this purpose discussed at some length. Cynodon dactylon is mentioned as being of value in this region, together with several other less common grasses.

Permanent pastures on lowland moors, W. Freckmann (Mitt. Ver. Förd. Moorkultur Deut. Reiche, 34 (1916), Nos. 1, pp. 7-11; 2, pp. 24-32).—This is a general discussion of the management of permanent pastures on low-lying moor lands. The division of the pasture into separate units, thus allowing alternate grazing, is recommended and the recommendation supported by experimental data.

A comparison of results obtained from pasturing young stock continuously on the same pasture, and alternating the pasture as indicated above, showed an increase of 80.78 marks per hectare (about \$7.79 per acre) in favor of the latter method. Other arguments advanced in favor of this system are that the forage in the pasture is more fully utilized, the vigor of the animals is increased, the care of the pasture is made easier through a better distribution of the manure and the use of the roller after the animals are removed, and the alternate removal of the crop of the permanent pasture, as secured by this system, has (with not too frequent repetition) a favorable influence on the pasture flora.

Some study has been made of fertilizing permanent lowland moor pastures with commercial fertilizers, indicating that good results may be expected.

Green manuring in India, A. C. Dobbs (Agr. Research Inst. Pusa Bul. 56 (1915), pp. 55, pls. 7, figs. 2).—This is a comprehensive discussion of the theory and practice of green manuring as applied to agricultural conditions in India, consisting chiefly of a compilation of data from various sources.

Color variation in seed crops of cultivated legumes, F. G. GALANG (Philippine Agr. and Forester, 5 (1916), No. 3, pp. 79-101).—This is a preliminary report of an attempt at simple selection with certain legumes, based on seed color. The crops used were as follows: Vigna sinensis (three varieties), Glycine hispida, Cyamopsis psoraleoides, Phaseolus calcaratus, P. lunatus, Psophocarpus tetragonolobus (two varieties), Dolichos biflorus, Centrosema plumicri, and Cajanus cajan. The color of the original seed planted is described in detail for each variety, and the color variations obtained from the different colored seeds of the different varieties are tabulated and discussed for each group of seeds, but no definite conclusions are drawn.

Alfalfa in Wyoming, T. S. Parsons (Wyoming Sta. Bul. 111 (1916). pp. 19-55, figs. 6).—The field practices employed in the production of alfalfa in Wyoming are discussed in detail, and variety and cultural tests for 1911 to 1915, inclusive, are reported.

The field experiments for each year of the five-year period are outlined and the results briefly summarized. Grimm alfalfa gave an average yield of 5.25 tons per acre for the 5-year period, leading all other varieties in yield, hardiness, and earliness of maturity. Broadcasting gave as good results as drilling the seed. Summer fallow put the soil in the best condition for alfalfa. An average hay yield of 1 ton per acre was obtained the first year when a nurse crop was used. No advantage was gained from liming or from inoculation on the experimental plats at Laramie. A seeding rate of 10 lbs. per acre was found ample in all cases, and one irrigation per cutting was usually sufficient. A well-packed seed bed with a loose surface, good seed, and sufficient moisture to insure germination are deemed to be the essential factors for successful alfalfa growing under conditions similar to those on the station farm.

Barley in Washington, E. G. Schafer and E. F. Gaines (Washington Sta. Bul. 141 (1917), pp. 3-12, figs. 3).—Comparative observations of winter and spring wheat, spring oats, and winter and spring barley for 1914, 1915, and 1916 indicate that spring barley produces the heaviest yields, while winter barley matures 12 days before winter wheat, 20 days before spring oats, 23 days before spring wheat, and 10 days before spring barley. The short growing season renders the crop well adapted to high altitudes.

Sixteen barley varieties are briefly described and the results of nursery and field tests reported. The covered six-rowed bearded varieties proved more productive than the naked six-rowed hooded varieties.

Corn experiments in 1915, P. R. Fedorov (Bezenchuk. Selsk. Khoz. Opytn. Sta. No. 75 (1916), pp. 6).—Experiments for the past two years show that the local (Samara) varieties of corn yield the higher in dry seasons, mature better, contain smaller percentages of water, and keep better than varieties imported from warmer and more humid regions. The latter, however, give higher yields in seasons with high humidity.

Cotton experiments, 1916 (Mississippi Sta. Bul. 178 (1916), pp. 3-40, figs. 3).—Suggestions for cotton culture in different parts of Mississippi are presented and the results of cotton experiments conducted at the Mississippi Station and the Holly Springs and Delta substations reported as heretofore (E. S. R., 34, p. 830).

In variety tests at the main station Express-350, with a yield of 674 lbs. of seed cotton per acre, and Express-341 and Foster-120, with yields of 672 lbs. each, were the leading varieties. Holdon, with a yield of 187 lbs., was lowest. The medium early big boll varieties Wannamaker-Cleveland, Cleveland Big Boll, and Miller are recommended for the hill portion of the State, due to good qualities exhibited in tests extending over a number of years.

At the Holly Springs substation, on valley land Trice, with a yield of 1,872 lbs. per acre, and Express-350, with 1,827 lbs., were best. Holdon, with a yield of 995 lbs., was lowest. On hill land Wannamaker-Cleveland was first, with 860 lbs., and Sproull Big Boll lowest with 600 lbs. Wannamaker-Cleveland, Trice, Express, and Unknown are recommended for the valley land of this district.

Results of variety tests at the Delta substation showed Lone Star-132 and Express-350, with yields of 992 and 961 lbs. per acre, respectively, to be first, with Holdon lowest with a yield of 292 lbs. Express, Allen Unknown, and Foster-120 are recommended as good varieties for the Delta district.

Further tabulated data show the variety averages from the three localities, the rank of varieties grown for the last six years on a basis of the money value per acre at each, the average length of certain varieties grown for six years, and the quantity of cotton ginned annually per county in Mississippi from 1907 to 1916.

Variety selections and individual selections of hybrids at the main station are reported in an effort to secure wilt-resistant strains and strains that could be grown profitably under boll-weevil conditions. Covington-Toole has given good results under wilt conditions but matures too late for regions badly infested with weevil. Wannamaker-Cleveland is reported as being an earlier-maturing strain and as also possessing good wilt-resistant qualities.

Spacing tests were conducted with varying results. At the main station the best yields were secured from rows 3 ft. apart, with 12 in. between plants in the row, while at the Holly Springs substation 3.5 ft. between rows gave the best yields. Conflicting results were secured at the Delta substation, but in every case the thinned rows outyielded the unthinned rows. Extensive tests of the single-stalk method of cotton culture were conducted at the main station and results obtained comparable with those of Cook (E. S. R., 31, p. 433), Meade (E. S. R., 33, p. 730), and others.

Methods for the development and maintenance of good cotton varieties are briefly outlined and the danger of deterioration of cotton seed at the public gin emphasized.

Extension of cotton production in California, O. F. Cook (U. S. Dept. Agr. Bul. 533 (1917), pp. 16).—This bulletin discusses the possible development of the cotton industry in California, with special reference to the long-staple types of cotton.

A brief history of cotton growing in California is given. Recent demonstrations have been made in the Imperial Valley and the Colorado Valley in extreme southern California, but the San Joaquin and other northern valleys contain much larger areas of irrigated and readily irrigable land available for cotton production.

Experimental plantings indicate that the Egyptian type can be grown in the southern part of the San Joaquin Valley, while in the northern parts Durango, or other long-staple Upland varieties, are more likely to succeed.

The labor requirements and other economic phases of cotton production are discussed. The author believes that the cost of labor is not so much a limiting factor as the scarcity, but also believes that the less acute demands made by

the cotton crop render it well adapted for use in a practical cropping system of diversified agriculture.

It is urged that any undertaking to establish the cotton industry in these regions be a community undertaking with a strongly centralized organization, similar to that existing among the fruit growers, for the control of the gins and oil mills, marketing of the crop, and dissemination of information relative to the production of the crop.

Cotton species indigenous to Italian Somaliland, G. E. MATTEI (Bol. R. Giard. Colon. Palermo, 2 (1916), No. 4, pp. 221-224, fig. 1; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 5, p. 683).—Two varieties of cotton said to be indigenous to Italian Somaliland are described by the author. The varieties are Gossypium paolii and G. benadirense. A brief summary of other species of Gossypium previously described as native to this region is given.

Tests and selections of mungo beans, L. A. SAN MIGUEL (Philippine Agr. and Forester, 5 (1916), No. 5, pp. 164-179).—Variety tests of mungo beans, Phaseolus sp., in the Philippines are reported, and the species found there are classified and described. Fertilizer tests were also conducted indicating that this crop thrives best with no fertilization, or with the addition of ashes alone.

Experiments with the overhead electrical discharge in 1915, I. Jorgensen (Jour. Bd. Agr. [London], 23 (1916), No. 7, pp. 671, 672).—This is a brief note on the effect of overhead electrical discharges on a crop of oats in 1915. The experiments were conducted by Miss E. C. Dudgeon, and are a continuation of work previously noted (E. S. R., 30, p. 827). The crop was grown on two 1.5-acre plats lying side by side, one plat receiving the electrical discharge and the other serving as a "control." The two plats were separated by a well-earthed wire screen which reached to a height of 3 ft. above the level of the charged network. The screen greatly reduced the amount of discharge reaching the nonelectrified area, but did not do away with leakage altogether. The discharge occurred for 557 hours during 108 days, or an average of about 5 hours per day.

The season was droughty and the soil light, but from the early stages the growth of the crop on the electrified area showed a superiority to that on the "control" area. An increase of 30 per cent in grain and 58 per cent in straw over the nonelectrified crop was obtained.

Contribution to the study of Panicum miliaceum, S. A. Belov (Bezenchuk. Selsk. Khoz. Opytn. Sta., No. 73 (1916), pp. 333-352, figs. 9).—This is a further contribution to botanical studies of the group Panicoideæ, with particular reference to flowering phenomena (E. S. R., 32, p. 727).

Observations are reported which indicate a close connection between the opening of the flowers and the meteorological conditions. The flower glumes were not observed to open on cloudy days having a high humidity. With high temperatures and low humidity on bright days flowering began at about 8 a. m., the flowers remaining open from 15 to 20 minutes. On days with similar temperature and moisture conditions, but with clouded skies, the flowers remained open about 25 minutes. Moderate heating of the flower with the sun's rays by means of a lens caused flowering to occur at 7 a. m. An excessive use of the lens, however, did not cause flowering, and after 11 a. m. acted negatively on flowers ready to open. Maximum flowering was observed from 10 to 11 a. m., diminishing rapidly from 12 to 12.30 p. m. Under intermediate conditions, even in the mean phase of flowering, flowering has been much more rarely observed than on bright warm days.

The anthers are reported as being even more sensible to changes in the external conditions.

The germination of the pollen on the stigma was accomplished 30 minutes after the closing of the flowers.

Notes are given on the color of the panicle and on the structure of the inflorescence and of the flower.

Field pea production, E. G. SCHAFER and E. F. GAINES (Washington Sta. Bul. 140 (1917), pp. 3-16, pl. 1, figs. 2).—The production and utilization of field peas are briefly discussed, and seven varieties described and comparative tests reported. The Bangalia variety has produced the largest yields for a four-year average, 31.8 bu. per acre.

The value of immature potato tubers as seed, H. P. HUTCHINSON (Jour. Bd. Agr. [London], 23 (1916), No. 6, pp. 529-539).—This is a general discussion of experimental work relating to the use of immature potato tubers for seed.

It is concluded that immature seed is superior because (1) in using immature tubers for seed the largest tubers of the most productive plants will naturally be selected, thus resulting in increased yields, or, at least, in maintaining previous yields. (2) The cortex of immature tubers is thinner than that of mature tubers, thus lessening the check on the imbibition of water from without, which is necessary during the early stages of growth. (3) The amount and availability of the reserve plant food material may be greater in the immature tubers than in the mature ones. (4) The length of time of storage may materially affect the amount and form of plant food material, which would favor immature tubers due to the longer period of storage to which they are subjected. The use of immature tubers for seed also promotes earliness, vigor, and an ability to form tubers under adverse seasonal conditions.

Directions are given for procuring and storing immature tubers.

Fertilizing the potato crop, C. E. Thorne (Mo. Bul. Ohio Sta., 2 (1917), No. 5, pp. 142-146, fig. 1).—The results of fertilizer experiments at the station with potatoes and wheat in a 3-year rotation of potatoes, wheat, and clover, extending over a 23-year period, are summarized and discussed.

An 1,100-lb. application for each 3-year period, carrying 50 lbs. of nitrogen, 30 lbs. of phosphorus, and 123 lbs. of potassium, half the nitrogen and two-thirds each of the phosphorus and potassium being applied to the potatoes and the remainder to the wheat, resulted in an average production of 190 bu. of potatoes per acre for the first 12 years and 159 for the remaining 11 years, while the wheat yields were 37.3 and 38.5 bu., respectively. When the total application was made on the potatoes the average yields were 187 and 155 bu. for the potatoes and 36 and 37 bu. for the wheat, respectively.

Applications of 8 tons of yard manure to the potatoes, with no further treatment for wheat, resulted in yields of 188 and 159 bu. per acre of potatoes and 30.3 and 33.8 bu. of wheat. Applying the manure to the wheat instead of the potatoes resulted in potato yields of 175 and 129 bu. and wheat yields of 30.4 and 36.8 bu., respectively. Applications of 16 tons of yard manure all applied to wheat resulted in yields of 192 and 175 bu. of potatoes and 34 and 37.5 bu. of wheat. In total effectiveness the 16-ton manure application exceeded the 1,100 lbs. of fertilizer by from \$3 to \$4 per acre for the first period and by from \$4 to \$7 for the second period.

Land left continuously without fertilizer or manure yielded at the rate of 166 bu, of potatoes per acre for the first period and 103 bu, the second period, the 63-bu, decrease being attributed largely to the growing of potatoes at too frequent intervals on the same land. It is recommended, therefore, that potatoes be planted on a good clover sod on land on which potatoes have not been grown for five or six years; that from 12 to 16 tons of manure be plowed under and supplemented with 300 lbs. of acid phosphate applied broadcast; and that

if manure is scarce 4 or 5 tons supplemented with 400 lbs. of acid phosphate and 100 lbs. of nitrate of soda be used.

Potato growing, S. N. Green (Mo. Bul. Ohio Sta., 2 (1917), No. 5, pp. 147-152, figs. 2).—The factors tending toward larger yields of potatoes under more intensive cultural methods are discussed. The seeding of small tubers (less than 2 oz.) gave an increase of 5.7 bu. per acre over the check (cut pieces of 2 oz.) as compared with an increase of 17.5 bu. from large (more than 6 oz.) tubers. This indicates that potato culls can be profitably utilized for seed, although their continued selection for seed is not recommended. The use of potato eyes only for seed is considered practicable under intensive cultural methods.

The yields from seven different planting dates ranging from May 17 to June 30 are compared with those of plantings made May 10 as a check. The May 17 planting gave an increase of 12.4 bu. per acre, while each succeeding planting gave decreased yields as compared with the checks ranging from 4.5 bu. for the plantings of May 24 to 44.8 bu. for those of June 30. Where late plantings were unavoidable the yields were greatly increased by exposing the bud end of the seed stock to a partial light, allowing short, green sprouts to develop. Plantings on June 30 from such seed yielded only 4.3 bu. less than plantings made May 10.

The 2-year average yields of marketable tubers of 41 varieties grown at Wooster and considered suitable for intensive culture are reported in tabular form. The average yields varied from 71.9 bu. for Eureka Extra Early, a Cobbler type, to 287.1 bu. for Livingston, a Rose type.

Potato growing in the loess area of the southwest, A. P. ZAPOBOZHENKO (Kiev. Agron. Obshch., Trudy Kom. Izuch. Khoz. Iugo-Zapad. Kraŵ, 4 (1915), pp. 1-118).—This is a detailed study of potato growing in the loess area of southwestern Russia. The cost of production has been determined in detail for a number of individual producers, and the results indicate a considerable lack of uniformity in the cultivation of the crop. The author concludes that the present type of potato culture in this region is not dependent on soil conditions and that it can be materially altered.

Fertilization of rice, C. Balangue y Rulloda (Philippine Agr. and Forester, 5 (1916), No. 5, pp. 144-158).—Fertilizer trials are reported with upland and lowland rice at three centers in the Philippines, using wood, grass, and rice ashes; stable manure; acid phosphate; ammonium sulphate, and lime. The results obtained from the various fields are reported in tabular form and discussed. Simple systems of fertilization of both upland and lowland rice were found profitable. Stable manure proved to be the best of the locally available fertilizers, with ashes next, and a combination of stable manure and ashes giving good results. Liming increased production, especially on the "old" fields.

Grain sorghums, B. A. Madson (California Sta. Bul. 278 (1917), pp. 227-250, flgs. 6).—The adaptation, production, and value of the grain sorghums in California are discussed in detail.

Variety tests for grain production were conducted at Davis from 1913 to 1916, inclusive, with 6 varieties of durras, 6 of Kafir corn, 4 of kaoliangs, and 1 of shallu. The highest average yield per acre was obtained from Dwarf milo maize, 3.575 lbs. Of the Kafir corns, Dwarf Blackhull was first with 1,962 lbs., and of the kaoliangs Brown with 2,962 lbs. Shallu averaged 3,542 lbs.

The highest average yield of both grain and stalk for 1914 and 1915, of the seven kinds most suitable for forage purposes, was secured from Blackhull White Kafir corn, 16.06 tons per acre, with feterita lowest, with 7.01 tons.

The best results were obtained from plantings made between April 10 and 20, with the planting rate varying from 4 to 7 lbs. per acre, depending upon conditions.

The composition of 5 varieties of durras, 3 of Kafir corn, 4 of kaoliang, and 1 of shallu grown in 1914 is reported in tubular form and compared with similar analyses of corn and barley. It is concluded that grain sorghums fed either as grain fodder or silage are but slightly inferior to corn in feeding value.

Second-growth sorghums may develop stock poisoning properties, but first crops seldom do, if ever, while the dried forage is entirely free from any harmful substances.

Sugar beet plantations in the peasant husbandry, M. Novinskii (Kiev. Agron. Obshch., Trudy Kom. Izuch. Khoz. Iugo-Zapad. Kraia, 3 (1915), pp. 5-40).—The author advocates the cultivation of sugar beets among the peasants of these southwestern Provinces of Russia, since the supply of land is limited, and they could by this means eliminate the 3-year rotation system and at the same time improve the land by the deep and careful cultivation that sugar beets demand. Cooperation among the large planters, sugar factories, and peasant growers is urged. Projects of agreements to be made between the beet producers and the sugar factories are submitted. It is pointed out that sugar beet culture would also aid the peasant in the feeding of his cattle.

[Sugar cane], H. P. AGEE (Hawaii. Sugar Planters' Sta. Rpt. Expt. Sta. Com., 1916, pp. 19-25).—The results from the Waipio experiments with sugar cane, together with various plantation experiments dealing with fertilizer and variety tests, are reported, and the field experiments now in progress are listed.

Further observations on the cultivation of Helianthus annuus, C. TROPEA (Bol. R. Giard. Colon. Palermo, 2 (1916), No. 4, pp. 214-220; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 5, pp. 686, 687).—This is a brief report of some tests with varieties of Russian sunflowers producing white seed, black seed, and variegated colored seed, the plants being classified entirely according to color of seed.

Fertilizer tests with tobacco varieties on college soils, G. Palafox y de la Cuesta (*Philippine Agr. and Forester*, 5 (1916), No. 2, pp. 50-59).—A series of fertilizer trials with five varieties of tobacco in the Philippines is reported.

All the varieties used responded creditably in height, vigor, and yield to fertilizer treatment. The largest gains were realized from the use of stable manure alone and legumes alone. From an economic standpoint green manuring with cowpeas and the use of stable manure was the cheapest source of material for obtaining increased production. Applications of commercial fertilizers by large growers are recommended.

Variability of tobacco in cultures on the college farm, A. B. Cagurangan (*Philippine Agr. and Forester*, 5 (1916), No. 2, pp. 60-64).—This is a summarized report of work conducted at the Philippine College of Agriculture to study the variations in leaves and habits of growth of the Texas Cuban, Lowland Turkish, Connecticut Havana, and Tirona Hybrid tobaccos grown on the college farm, and to determine what forms in each variety are most desirable for selection. The conclusions arrived at from these studies are regarded as thus far of rather local importance.

The production of cigar wrapper tobacco under shade in the Philippines, D. B. PAGUIRIGAN Y AMALINGAN (Philippine Agr. and Forester, 5 (1916), No. 2, pp. 39-49).—In these experiments, the native varieties Cagayan and Tirona Hybrid and the acclimatized foreign varieties—Turkish Lowland, Vuelta Abajo, Sumatra, and Texas Cuban—were grown both in the open and under shade.

The native varieties gave the best results, the leaves produced under shade being classified as almost "ideal" in quality for wrapper purposes. The burning qualities of Cagayan, Sumatra, and Tirona Hybrid were improved when shaded, while the other varieties showed no response to shading. The length of the leaves and height of the plants was considerably increased by shading, but the weight of the unshaded leaves was the greater.

General recommendations are made for tobacco culture in the Philippines.

Tobacco.—The production of light-colored pipe and cigarette leaf, C. J. TREGENNA (Dept. Agr. N. S. Wales, Farmers' Bul. 106 (1915), pp. 14).—This is a general discussion of the production of tobacco in New South Wales.

Wheat, N. Schmitz (Maryland Sta. Bul. 198 (1916), pp. 59-94, figs. 11).— The field practices employed in the production of wheat in Maryland are discussed at some length, and variety tests conducted in cooperation with the U. S. Department of Agriculture, extending over the period of 1908 to 1916, inclusive, are reported. The tabulated data show the annual and average yields per acre of grain and straw for the 24 varieties remaining in the test through 1916. Further data show the yields of 78 varieties which have been discarded from time to time since 1908. Descriptions are included of several varieties.

The highest average yield for the 9-year period was obtained from Bearded Purple Straw, 29.87 bu. of grain and 1.77 tons of straw per acre. China, Dietz Longberry, Currell Prolific, and Mammoth Red followed in the order named, with average yields of grain of 29.66, 29.37, 29.27, and 28.94 bu., respectively. The lowest average yield was secured from Miracle, 20.09 bu., in a 5-year test, seeded at the rate of 2 pk. per acre.

The more common diseases and insect pests of wheat are briefly described and control measures are recommended.

The effect of soil moisture content on certain factors in wheat production, F. S. HARRS and H. J. MAUGHAN (*Utah Sta. Bul. 152 (1917)*, pp. 3-15, figs. 15).—Supplementary to work previously noted (E. S. R., 32, p. 814; 36, p. 234), experiments are reported on the water requirements of wheat conducted during 1913, 1914, and 1915 in large tanks, previously described (E. S. R., 22, p. 425.).

The life of the wheat plant was divided into three periods, as follows: From planting to the five-leaf stage, from the five-leaf stage to the boot stage, and from the boot stage to maturity. The results of the experiments are presented in 15 figures, the lower part of which represent the average moisture content of the soil during each of the three periods in the growth of the crop. The effects of the moisture treatments are noted on yield of grain, weight of straw, yield of dry matter, number of kernels produced, weight of 100 kernels, number of heads produced, length of heads, number of kernels per head, weight of grain per head, amount of tillering, height of plants, date of maturity, and evaporation and transpiration of water. The moisture treatments for the different periods varied from 7.5 to 35 per cent (saturation) of the soil.

The highest yield of grain was obtained on the soil having about 20 per cent moisture throughout the season. The wheat plant seems especially sensitive to soil moisture conditions during the period immediately preceding the boot stage.

The evaporation and transpiration from a soil producing a large crop was greater than from a free-water surface, but there was a greater loss from the water surface than from the soil producing only a small crop. The importance of favorable soil moisture conditions to good wheat yields is apparent, the yield being more than 20 times as great with proper soil moisture conditions as with unfavorable conditions. Excessive soil moisture was as detrimental to good yields as a lack of sufficient soil moisture.

Gluten formation in the wheat kernel, G. A. Olson (Washington Sta. Bul. 142 (1917), pp. 3-19).—After briefly reviewing previous work, the author presents data which tend to show the formation of gluten in the wheat kernel to be due to the synthetic activity of an enzym. The experiments included a study of the effect of temperature on the formation of gluten in Jones Winter Fife and Red Russian wheat in 1914, and in Red Russian and Turkey Red X Bluestem (Washington No. 536) in 1915, of the various forms of nitrogen groups separated from the flour of the 1914 crop, of the effect of heating for various lengths of time on the formation of gluten in Marquis wheat in 1915, and of the amino nitrogen in Red Russian wheat in 1915. The wheat samples were selected in an early stage of development to determine whether or not gluten was present as such or developed in the kernel as a final product of protein synthesis. The wheat was desiccated at varying temperatures and under varying conditions, including air-drying at room temperature, heating in vacuum pans, and heating in an oil bath.

Positive evidence that gluten was formed within the kernel and not translocated as such from other regions of the plant was obtained in the 1914 experiments. Fife wheat air-dried at a room temperature of 20° C. showed 24.2 per cent wet gluten and 10 per cent dry gluten, while that heated at from 50 to 60° showed only 1.4 and 0.7 per cent, respectively. Samples collected six days later than those noted above and air-dried at 20° showed 27.3 per cent wet and 11 per cent dry gluten. These larger yields are attributed to the translocation or formation of additional material out of which gluten was formed. A temperature range from 30 to 35° under reduced pressure did not materially affect the transformation, the percentages of wet and dry gluten being 22.5 and 9.6 respectively, while with a temperature of 40° or over the percentage was reduced 50 per cent or more. Comparable results were obtained with Red Russian wheat.

In an effort to determine whether or not the protein materials in the kernel were affected by different temperatures the separation of the protein groups was made by the author's method (E. S. R., 31, p. 208). The results obtained indicate that the synthesis of the more complex nitrogenous substances was not complete at the time of harvest, and that the samples heated to a temperature which suppressed the transformation of the materials into gluten contained the largest amounts of amid nitrogen. Since these samples were exposed to relatively high temperatures under reduced pressure it would be expected that under normal pressure the destructive temperatures would be considerably lower.

The 1915 experiments conducted in an oil bath obviated reduced pressures and, in addition to the 1914 observations, moisture determinations were made on all samples. Red Russian wheat air-dried at room temperature showed 23.5 per cent wet and 10.4 per cent dry gluton. Samples containing 65 per cent moisture failed to yield any gluten when heated as low as 40° for 30 minutes. With a reduction in the moisture content some gluten was formed. Samples heated at 50° for 30 minutes after 66 hours desiccation and having 44.73 per cent moisture yielded 13.3 per cent wet and 6.6 per cent dry gluten.

While enzyms that will cause the formation of gluten have not been isolated, the author believes them to be the active agent. Gluten formation is inhibited by heating to relatively low temperatures, 40 to 45°, and desiccation accelerates gluten formation through the concentration of a solution of the materials upon which the enzym acts. The enzym may be present in the kernel from a very early stage but not functional until the soluble nitrogenous materials in the kernel have became concentrated through a rapid translocation from the leaves, and through desiccation,

The results obtained from Washington wheat No. 536 indicated that the wheat was too nearly matured for a satisfactory study of enzymatic action, but further confirmed the results noted above regarding the formation of gluten in the presence of considerable moisture. A comparison of the temperature effects obtained for the first day of harvest showed that heating to 35° was as effective in inhibiting gluten formation as was heating to 50 or 55°, indicating that a temperature of 35° is destructive to the gluten-forming enzym.

Samples of Marquis spring wheat were subjected to temperatures of from 40 to 50° for periods of 5, 10, 20, and 30 minutes, but further observations are considered necessary before attempting to establish the relationship of temperature and moisture content of grain to gluten formation.

Wheat subjected immediately to temperatures ranging from 40 to 55° showed more nitrogen in the amino form than wheat heated to 50° after intervals of 24, 48, and 66 hours.

Spraying of charlock in corn (Univ. Col. No. Wales, Bangor, Dept. Agr. [Pub.] 7 (1915), pp. 2-6).—Cooperative spraying tests at numerous centers in North Wales for the eradication of charlock in corn are reported. A 4 per cent solution of copper sulphate is recommended, applied as a fine spray when the weed is in full bloom.

#### HORTICULTURE.

Horticultural laws of the State of Washington (Olympia, Wash.: State, 1915, pp. 32).—The text of the laws enacted in 1915 is given.

Luther Burbank, his methods and discoveries and their practical application, edited by J. Whitson and R. J. and H. S. Williams (New York and London: Luther Burbank Press, 1914 vols. 4-9, pp. 308, pls. 105 each; 1915, vols. 10-12, pp. 308, pls. 105 each).—The first three volumes of this work have been noted (E. S. R., 32, p. 143).

The garden, S. B. Shaw (Md. Agr. Ext. Serv. Bul. 3 (1917), pp. 57-67, figs. 4).—A popular bulletin on vegetable gardening including directions for the use of spray materials in small quantities.

The home garden in Kentucky, C. S. Adams (Kentucky Sta. Circ. 14 (1917), pp. 9-59, figs. 19).—A practical treatise on vegetable gardening, including a discussion of the general principles and directions for growing the more important vegetables.

Variation in artichokes, A. D. SHAMEL (Jour. Heredity, 8 (1917), No. 7, pp. 306-309, figs. 2).—The author points out and illustrates instances of variation in the plants and flower heads of globe artichokes, and suggests the opportunity for improving these plants through bud selection.

Experiments in keeping asparagus after cutting, F. W. Morse (Massachusetts Sta. Bul. 172 (1917), pp. 297-307).—The author conducted a number of experiments to determine the changes which take place in asparagus when stored under different conditions from the time when it is cut in the field until it is ready to be cooked. Data are given showing the weight when fresh as well as the loss in weight of dry matter and total sugars from dry matter after storage.

The results show in substance that asparagus stalks will become limp even when on ice unless their butts are in water or some other means are taken to reduce the evaporation to the lowest point. Even when the butts are placed in water there is loss, both in dry matter and total sugars from dry matter. This loss is greater under room temperatures than under refrigeration. The weight of stalks placed in water under room temperature increased more than those placed in water under refrigeration. By placing the stalks under refrigeration.

eration in a close atmosphere it was found possible to hold asparagus for a week with very little deterioration in quality. The temperature should be as low as 45° F. if possible in order to check plant growth. The usual methods of keeping asparagus at summer temperatures cause rapid deterioration in quality.

Although experiments on a commercial scale have not been tried, the present experiment led to the suggestion that the asparagus be cooled as soon as possible after cutting. The stalks may be laid loosely in boxes, placed on ice in the ice house, and covered with canvas to maintain a low temperature and reduce the circulation of air.

New Mexico beans, F. Garcia (New Mexico Sta. Bul. 105 (1917), pp. 56, figs. 15).—A treatise on bean culture, including notes on varieties adapted for New Mexico conditions, and analyses showing the protein content of various types. Reports by various county agents relative to local methods of culture in several counties of the State are appended.

Report of the experimental work of the Taliparamba Agricultural Station for 1913-14, H. C. Sampson (Dept. Agr. Madras, Rpt. Taliparamba Agr. Sta., 1913-14, pp. 13).—Data are given on manurial experiments with peppers conducted at the station for a number of years, together with an account of the local agriculture in the neighborhood of the station.

Report of the work of the Taliparamba Agricultural Station for 1914-15, H. C. Sampson (Dept. Agr. Madras, Rpt. Taliparamba Agr. Sta., 1914-15, pp. 11).—A report on pepper fertilizer experiments similar to the above for 1914-15.

Report of the work of the Taliparamba Agricultural Station for 1915-16, K. RAMASASTRULU NAYUDU (Dept. Agr. Madras, Rpt. Taliparamba Agr. Sta., 1915-16, pp. 12).—A report on pepper fertilizer experiments similar to the above for 1915-16.

The tomato as a farm crop for the canning factory, H. J. Reed (Indiana Sta. Circ. 59 (1917), pp. 28, figs. 13).—This circular is based on investigations by the station previously reported (E. S. R., 29, p. 434; 30, p. 738), supplemented by further field studies. It deals particularly with the culture of tomatoes with reference to their sale to canning factories.

[Vegetable seed production at Vineland, Ont.] (Agr. Gaz. Canada, 4 (1917), No. 5, pp. 397, 398).—A brief statement of progress made in the home production of vegetable seed at the Horticultural Experiment Station at Vineland, Ont. Tests made by growers in 1916 of seed produced in 1915 indicate that germination in the home seed of a number of vegetables was in most cases 20 per cent or better than that of other seed.

New or noteworthy fruits, V, U. P. Hedrick (New York State Sta. Bul. 427 (1916), pp. 523-529, pls. 5).—This is the fifth of a series of bulletins (E. S. R., 35, p. 36) dealing with new or noteworthy fruits under observation at the station. The present bulletin describes and illustrates the J. H. Hale and Pearson peaches, Drap d'Or plum, Empire raspberry, and Good Luck strawberry.

Variety testing at the Dominion Experimental Farms, and what has been accomplished by it, W. T. Macoun (Agr. Gaz. Canada, 4 (1917), No. 5, pp. 349-354).—A popular review of results secured from long-continued variety tests of orchard and small fruits at the Canadian Experimental Farms.

Varieties of fruit in the Province of Starkenburg (\$\( \textit{L} \) rb. Landw. Kammer Hesse, No. 19 (1915), pp. 64, pls. 30).—This comprises a list of varieties of orchard and small fruits recommended for culture in the Province of Starkenburg, Hesse. A number of the more important varieties are illustrated by colored plates.

Studies in fruit bud formation, J. R. Magness (Ann. Rpt. Oreg. State Hort. Soc., 8 (1916), pp. 98-105).—A paper on this subject, with a discussion follow-

ing, based upon the author's investigations previously noted (E. S. R., 36, p. 237).

The freezing of fruit buds, F. L. West and N. E. Edlefsen (Utah Sta. Bul. 151 (1917), pp. 3-24, figs. 6).—This bulletin reports methods used by the authors in conducting freezing studies of detached branches and also of whole trees. The results obtained on between 5,000 and 6,000 buds of apples, peaches, cherries, and prunes are reported and the literature on the subject is reviewed.

In addition to improving the methods of freezing buds in the laboratory an equipment was devised for freezing branches without removing them from the tree. It was also found that the whole tree could be frozen under natural conditions by surrounding it with a tank of ice and salt. The factors that enter into the problem are thus satisfactorily controlled and accurately determined. Frost damage can be measured by the injured buds and also by the yield of fruit in the fall.

The investigation shows that the fruit buds in the same orchard do not have a uniform freezing point. An orchard can usually stand two or three freezes without losing more than half of its buds, thus leaving enough buds for a normal fruit crop.

Data are given on some preliminary studies with Jonathan apples and Elberta peaches. The results show in general that the further developed the buds are the more sensitive they are to frost. There is a range of at least 5° F. between the temperature at which only about 5 per cent of the buds are damaged and the temperature that will kill all of them. With Jonathan apples in full bloom, 28.5° caused no damage and 24° killed about half of the blossoms. The following temperatures will kill about 50 per cent of Elberta peach buds in various stages of development: When they are slightly swollen, 14°; when well swollen, 18°; when they are showing pink, 24°; when they are in full bloom, 25°; and when the fruit is setting, 28°. In the case of Double Nattie cherries 29° caused no damage when the fruit was setting but 24° killed practically all of them. Prune buds are slightly hardier than those of the other kinds of fruit tested.

Pruning fruit trees, W. H. ALDEBMAN and E. C. AUCHTER (West Virginia Sta. Bul. 164 (1917), pp. 3-40, figs. 33).—The purpose of this bulletin is to present simple and practical directions for pruning based upon the most recent information available. In addition to a discussion of the general principles of pruning directions are given for pruning and training the apple, peach, cherry, plum, pear, and quince at the time of planting and in subsequent years. Some of the data secured in the station's recent experiments in pruning apple trees (E. S. R., 36, p. 535) are also included.

The Taylor system of pruning, A. TAYLOR (San Jose, Cal.: Eaton & Co., 1917, pp. 79, pl. 1, figs. 38).—A treatise on pruning fruit trees with special reference to California conditions, based on the author's experience extending over a period of 25 years.

The influence of pruning upon the fruit spur system of the apple, V. R. GARDNER (Ann. Rpt. Oreg. State Hort. Soc., 8 (1916), pp. 66-72).—A popular discussion of this subject, based upon the author's investigations previously noted (E. S. R., 36, p. 237).

The influence of commercial fertilizers on bearing apple orchards, G. G. Brown (Ann. Rpt. Oreg. State Hort. Soc., 8 (1916), pp. 36-41).—A popular summary of the author's investigations, previously noted (E. S. R., 37, p. 41).

The selection and hybridization of American vines in Italy, G. PATANÉ (Internat. Inst. Agr., [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 10, pp. 1393-1404).—An account of the results secured with American species of grapes in the reconstitution of phylloxera-infested vineyards in Italy.

Comparative merits of California avocado varieties, L. B. Scott (Cal. Citrogr., 2 (1917), No. 8, pp. 2-4, figs. 4).—An address delivered before the California Avocado Association.

Based on their performance records the author is of the opinion that the number of varieties for commercial plantings should be greatly reduced. Of a great number of varieties under observation only nine, the Sharpless, Fuerte, Surprise, Spinks, Taft, Monroe, Lyon, Blakeman, and Dickinson, appear to approach the requirements of an ideal avocado.

Avocado varieties in Florida, E. D. Vosbury (Cal. Citrogr., 2 (1917), No. 8, p. 5, fig. 1).—A brief discussion relative to the adaptability of different avocado varieties to Florida conditions.

Report on cacao manurial experiments at Djati-Roenggo during the years 1912, 1913, and 1914, J. R. C. Peelen and A. W. K. de Jong (Meded. Proefstat. Midden-Java, No. 24 (1917), pp. 8, pl. 1).—The experiments here reported show that the use of stable manure resulted in only slight increases in yield, whereas the use of a combination of stable manure and superphosphate resulted in increased yields of from 40 to 50 per cent over the check plats.

The culture of citrus plants in Cuba, R. S. CUNLIFFE and H. A. VAN HERMANN (Estac. Expt. Agron. Cuba Bol. 32 (1916), pp. 62, pls. 44).—A treatise on citrus fruits with reference to soil and climatic requirements, methods of propagation, fertilization, culture, varieties, insect pests and diseases, methods of harvesting, marketing, and citrus products.

A lemon bud variation, A. D. Shamel (Jour. Heredity, 8 (1917), No. 6, p. 284, fig. 1).—The author here describes and illustrates a navel lemon produced by a normal tree bearing, except for this specimen, normal fruits.

Maturity standard for Washington navel, E. M. CHACE (Cal. Citrogr., 2 (1917), No. 9, pp. 7, 17, fig. 1).—A popular review of the work of the Bureau of Chemistry of the U. S. Department of Agriculture in the development of maturity standards for oranges, including a discussion of the effect of the different proposed standards.

A practical guide to coconut planting, R. W. Munro and L. C. Brown (London: John Bale, Sons & Danielsson, Ltd., 1916, pp. XX+186, pls. 103).— This work comprises an enlargement of the junior author's bulletin on the subject written in 1910 (E. S. R., 24, p. 40).

The genus Annona in the Hawaiian Islands, V. MacCaughey (*Torreya*, 17 (1917), No. 5, pp. 69-77).—A brief account of the adaptation of different members of the custard-apple genus that have been introduced into Hawaii.

Cultivation of the papaya, R. S. Cunliffe (Agriculture [Cuba], 1 (1917), No. 4, pp. 12-27, figs. 12).—Methods of propagating and growing papayas are described, including an account of the collection and preparation of papain from the fruit.

South American markets for fresh fruits, W. FISCHER (U. S. Dept. Com., Bur. Foreign and Dom. Com., Spec. Agents Ser., No. 131 (1917), pp. 163, pls. 7).— This report reviews fully the native fruit industry in Brazil, Argentina, Uruguay, Paraguay, Peru, and Chile, and discusses the development of the foreign fresh-fruit trade in those countries, with special reference to the possibility of opening new markets for the United States.

Making nuts in five years, T. P. LITTLEPAGE (Amer. Nut Jour., 6 (1917), No. 6, p. 87).—In this brief note the author reports the development of catkins on 3-year-old Busseron, Greenriver, and Major pecans growing in Maryland, indicating the probability of the trees bearing fruit at the age of 4 or 5 years.

Gladiolus studies.—III, Varieties of the garden gladiolus, A. C. HOTTES (N. Y. State Col. Agr., Cornell Ext. Bul. 11 (1916), pp. 275-451, pl. 1, figs. 31).—

In continuation of previous studies (E. S. R., 36, p. 643), this bulletin describes most of the varieties of gladiolus received for trial on the grounds of the Cornell University department of floriculture in cooperation with the American Gladiolus Society. The descriptions are preceded by an account of the methods used in testing and describing the varieties.

The culture of garden roses, A. C. Beal (Cornell Reading Course for the Farm, No. 121 (1917), pp. 189-215, figs. 17).—A popular treatise on rose culture.

Sweet peas up-to-date, G. W. Kebb (Philadelphia: W. Atlee Burpee & Co., 1917, rev. ed., pp. 100, figs. 16).—In addition to cultural directions a descriptive list is given of all varieties of sweet peas, as far as known, introduced up to 1917.

Milady's house plants, F. E. Palmer (New York: A. T. De La Mare Co., Inc., 1917, pp. 176, figs. 96).—A popular treatise on the selection, culture, and care of various house plants.

Putnam's garden handbook, MAE S. CROY (New York: G. P. Putnam's Sons, 1917, pp. V+359).—A popular manual of ornamental gardening.

The joyous art of gardening, Frances Duncan (New York: Charles Scribner's Sons, 1917, pp. XIII+239, pls. 8, figs. 54).—A popular treatise on the planning and planting of home grounds, designed especially for the amateur gardener.

"Know your city" trees, C. Bannwart (Newark, N. J.: Newark Shade Tree Com., 1916, pp. 20, figs. 14).—This comprises a directory of the noteworthy trees of Newark, N. J., with special reference to those of historic and special botanic interest.

#### FORESTRY.

Trees worth knowing, Julia E. Rogers (Garden City, N. Y.: Doubleday, Page & Co., 1917, pp. XXIII+291, pls. 48).—This comprises popular descriptive accounts of the principal trees of the United States. The trees are grouped as nut trees, water-loving trees, trees with showy flowers and fruits, wild relatives of our orchard trees, the pod-bearing trees, desiduous trees with winged seeds, the cone-bearing evergreens, and the palms.

A bud and twig key to the more important broadleaf deciduous trees in the United States, O. L. Sponsler (Ann. Arbor, Mich.: George Wahr, 1916, rev. ed., pp. 26, figs. 8).—About 85 species of the more important broadleaf deciduous trees, including the more important forest trees, as well as a few of the smaller trees and more common exotics, are given in the key.

The pine trees of the Rocky Mountain region, G. B. Sudworth (U. S. Dept. Agr. Bul. 460 (1917), pp. 46, pls. 42).—Supplementing a previous bulletin dealing with cypress and juniper trees (E. S. R., 33, p. 343), this bulletin comprises descriptions and illustrations of the distinguishing characteristics of all of the pine trees that inhabit the Rocky Mountain region. Graphic illustrations of the range of these trees and discussions of their forest habits are also included.

Note on the forests of Java and Madoera of the Dutch East Indies, R. C. Milward (Calcutta: Govt., 1915, pp. 8, pls. 5).—The note deals chiefly with the extent, silvical management, exploitation, yields, and revenues of teak forests in Java and Madoera.

Factors causing variation in the yield of camphor in the Florida camphor tree, S. C. Hoop (Jour. Indus. and Engin. Chem., 9 (1917), No. 6, pp. 552-555).—
The present paper is based on observations on camphor trees growing under various conditions in Florida during the years 1907 to 1912, at which time the author was on the scientific staff of the Bureau of Plant Industry of the U. S. Department of Agriculture. The paper presents the more important results having a direct bearing on the methods of commercial production of camphor.

The rubber industry, edited by J. Torrey and A. S. Manders (London: Internat. Rubber & Allied Trades Ex., Ltd., [1917], pp. 516, pl. 1, figs. 34).—
This book comprises as a whole the official report of the Fourth International Rubber Congress, held in London in 1914. In addition to the papers dealing with various phases of the rubber industry and the discussions thereon, numerous papers and discussions dealing with fibers, cotton, oils, etc., together with the principal papers read at the rubber congress held in New York in 1912 and a report of the proceedings of the Fourth International Rubber and Allied Industries Exhibition held in London in 1914, are also given.

A practical tapping experiment conducted on scientific principles, A. W. K. DE JONG (*Teysmannia*, 28 (1917), No. 1, pp. 30-32).—The results are given of comparative tests of a number of methods of tapping rubber that have been conducted for a period of three and one-half years.

Scientific tapping experiments with Hevea brasiliensis, A. W. K. DE JONG (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Agr. Chem. Lab., No. 14 (1916), pp. 26, figs. 14).—Two sets of experiments are reported. In one set various systems of tapping were compared on the same tree. In the other set the various systems of tapping compared were used on different trees.

Investigations of the quality of plantation rubber conducted under the Caylon rubber research scheme (Bul. Imp. Inst. [So. Kensington], 14 (1916), No. 4, pp. 495–566).—The investigations recorded in the present article were conducted under the auspices of the government of Ceylon in conjunction with some of the principal planting companies of the island and with the Imperial Institute. They deal with the effect upon the mechanical properties of the vulcanized rubber of different methods of coagulation, the addition of various substances to the latex in order to retard coagulation, the form of the rubber, the method of drying, "overworking" freshly coagulated rubber in the washing machine, various methods of smoking, drying sheet rubber under tension, rolling up wet and dry sheet rubber, with and without tension, the conversion of wet and dry crepe rubber into block, and separating the rubber from the latex in successive portions.

The influence of the rubber content of latex on the inner qualities of the rubber, O. DE VRIES (Arch. Rubbercult. Nederland. Indië, 1 (1917), No. 1, pp. 25-34).—Several experiments were made to determine what effect the dilution of latex has on the inner qualities of rubber. The tensile strength showed no difference, except in the case of a very diluted latex which gave a lower tensile strength. The viscosity was diminished slightly by dilution and the rate of cure in an appreciable degree. In view of the differences in rate of cure noted, it is held to be desirable to dilute the latex to a standard rubber content in order to obtain rubber of uniform qualities.

Influence of the amount of acetic acid on the inner qualities of the rubber, O. DE VRIES (Arch. Rubbercult. Nederland. Indië, 1 (1917), No. 1, pp. 35-41).— As a result of experiments conducted in part by the author and in part by P. Arens and N. L. Swart it was found that for quantities of acetic acid ranging from the minimum to four times as much the tensile strength of the rubber shows no difference. The slope or type of rubber remained the same in all experiments in which the rubber was prepared as crepe, although in one experiment with smoked sheet rubber the type was slightly less when using a double quantity of acetic acid. The viscosity increased slightly with increasing quantities of acetic acid. When four times the minimum quantity of acetic acid was used the rate of cure diminished to the extent of 10 minutes in 135.

It is concluded in brief that the small variations in amount of acetic acid used in actual practice can not be the cause of lack of uniformity in the rubber.

Sugar as a coagulant for crepe rubber, O. de Vries (Arch. Rubbercult. Nederland, Indië, 1 (1917), No. 1, pp. 5-16).—As a result of experiments conducted in part by the author and in part by N. L. Swart and A. J. Ultée the conclusion is reached that the difference between rubber coagulated by acetic acid and by sugar is insignificant. Such difficulties as arise in the practice of sugar coagulation can be overcome, and it is believed that sugar might possibly be the coagulant most fitted to replace acetic acid if necessary.

Reforestation on the National Forests, C. R. TILLOTSON (U. S. Dept. Agr. Bul. 475 (1917), pp. 63, pls. 12, figs. 4).—The present bulletin is based partially on Forest Service Bulletin 98 (E. S. R., 26, p. 241), which it supersedes, and partially on more recent results secured in the reforestation work of the U. S. Forest Service as a whole.

Nursery practice on the National Forests, C. R. TILLOTSON (U. S. Dept. Agr. Bul. 479 (1917), pp. 86, pls. 22, figs. 6).—This bulletin presents the results of the study and experience of many different members of the Forest Service. The subject matter is presented under the headings of factors influencing selection of a nursery site, size and arrangement of nursery, outfit, nursery operations, removal of planting stock from the nursery, diseases and injuries in the nursery, fertilizers, and costs of operations.

Latest devices in protection work, C. DuBois (Proc. Forest Indus. Conf., West. Forestry and Conserv. Assoc., 1916, p. 13).—A popular discussion of improvements in methods, equipment, and appliances employed in forest fire protection work.

The annual report of the National Forest Reservation Commission for the fiscal year ended June 30, 1916 ( $U.\ S.\ Senate,\ 64.\ Cong.,\ 2.\ Sess.,\ Doc.\ 643$  (1916),  $pp.\ 10$ ).—A report relative to the acquisition of lands for the protection of watersheds of navigable streams in the White Mountains and southern Appalachians during the fiscal year ended June 30, 1916. At this time 1,329,038 acres of land had been approved for purchase and 706,974.5 acres of land actually acquired at an average price of \$5.52 per acre.

Report of the State forester, M. Schaaf (Bien. Rpt. Pub. Domain Com. Mich., 1915-16, pp. 87-129, flgs. 14).—A progress report on State forest activities in Michigan covering the period from January 1, 1915, to June 30, 1916, including a brief description of the State forests, results secured from forest fire protection, nursery work, planting operations, etc.

First annual report of the State forester, J. H. Foster et al. (Bul. Agr. and Mech. Col. Tex., 3. ser., 3 (1917), No. 3, pp. 16).—A brief statement of progress made along the lines of forest protection, assistance rendered to private owners, educational work in forestry, and investigations, with suggested plans for improving the forestry work in Texas.

Report on the forest administration of the Central Provinces for the year 1915-16, H. H. FORTEATH, C. B. SMALES, and F. TRAFFORD (Rpt. Forest Admin. Cent. Prov. [India], 1915-16, pp. 3+29+49+XCVI).—This is the usual report relative to the administration and management of the State forests of the Northern, Southern, and Berar Circles, including a financial statement for the year.

All important data relative to alterations in forest areas, forest protection, forest surveys, miscellaneous work, yields in major and minor forest products, revenues, expenditures, etc., are appended in tabular form.

Organization and activities of the Chinese forest service, F. SHFRESEE (Indian Forester, 43 (1917), No. 5, pp. 205-221).—An account of the organization and functions of the six divisions into which the Chinese forest service is organized.

Timber storage conditions in the Eastern and Southern States with reference to decay problems, C. J. Humphrey (U. S. Dept. Agr. Bul. 510 (1917), pp. 42, pls. 10, figs. 41).—This bulletin embraces the results of a survey of timber storage conditions in the Eastern and Southern States, conducted with the view of securing data for a study of the effective control of decay in building timber. The subject matter is presented under the general headings of cause of decay in timber, handling timber at sawmills, location of mills and its relation to decay, quality of stock with reference to decay, condition of storage sheds at mills, condition of storage yards at mills, handling timber at retail yards, fungi which rot stored lumber, wood preservatives in the lumber-yard, and branding structural timber. A number of suggestions are given relative to the improvement of lumber storage conditions by modifying the present insanitary practices.

#### DISEASES OF PLANTS.

Report of the mycologist, R. H. Bunting (Govt. Gold Coast, Rpt. Agr. Dept., 1915, pp. 21-25).—It appears that the yield of the cacao trees on the old established farms is decreasing, and that this is due largely to the increase of cacao diseases. Pod rot (Phytophthora faberi, frequently associated with Diplodia cacaoicola) is considered as the most widespread and destructive of these diseases. A fungus resembling Colletotrichum cradwickii may be responsible for enormous loss from the withering of the young pods. Of somewhat less importance are the thread blights, Marasmius scandens and M. equicrinis. Important root diseases of cacao are due to Polyporus lignosus (Fomes semitostus), Hymenochæte noxia, and a species of Rosellinia. Numerous cases of die-back appear to be related only secondarily to fungi.

The most serious diseases of Hevea are due to root parasites, *P. lignosus*, *H. noxia*, *Sphærostilbe repens*, and a Rosellinia killing rubber trees at various points.

Other diseases noted, or suspected, are an undetermined mildew of Coffea liberica; brown rot (H. noxia) of C. stenophylla; white thread (M. scandens) on Coffea sp., soursop, and cola; Cercospora personata on peanut; bleeding disease (probably Thielaviopsis ethaceticus) of coconut; S. repens on jak fruit; P. lignosus on camphor, cassava, Combretum sp., and Irvingia sp.; Corticium sp. on Ficus elastica; and coffee-leaf disease (Hemileia vastatrix) on Strophanthus hispidus.

Parasitic diseases of cultivated plants, R. Renacco (An. Soc. Cient. Argentina, 81 (1916), No. 1-2, pp. 62-70).—A list is given, with a systematic arrangement according to relationships, of about 35 fungi parasitic on economic plants as observed, mostly during the latter part of 1914, in a portion of the Province of Buenos Aires.

Black mold of onions, W. Van Pelt (Mo. Bul. Ohio Sta., 2 (1917), No. 5, pp. 152-156, flg. 1).—A popular account is given of a new fungus disease which is said to cause serious damage in storage houses. The cause of the trouble is Aspergillus niger, the presence of which is indicated by the occurrence of small circular spots scattered over the onion, generally about the upper half. As the areas develop, there is formed a large diseased mass which often involves the greater part of the onion. The outer layers of the bulb become wrinkled, dry, and practically worthless. This condition, however, is rarely found except in storage. As a rule white varieties are most subject to infection, although the disease has been found on red ones as well.

Examination of samples of onion seed showed the presence of spores, and experiments in applying formalin to the affected seed proved that this fungicide

will control the trouble. It is recommended that the fungicide be applied by the drip method which is used for the prevention of onion smut. No efficient method has been determined for the treatment of onion sets, but experiments along this line are in progress.

Investigations on potato diseases (seventh report), G. H. PETHYBRIDGE (Dept. Agr. and Tech. Instr. Ireland Jour., 16 (1916), No. 4, pp. 564-596, pls. 12).—The special investigations on potato diseases, which were started in 1909 at Clifden, Ireland, and since reported on from time to time (E. S. R., 34, p. 443), were continued during 1915, and the results are here described in considerable detail.

Phytophthora infestans appeared very late in 1915, supposedly on account of the fine dry weather which prevailed after planting until the end of June, and after that time supposedly on account of the scarcity of infecting spores. From the work already done, it is thought that in favorable seasons, at least, the use of 1 per cent Bordeaux or Burgundy mixture is about as effective as is the 2 per cent application. Tests with a fungicidal powder showed this to be inferior to the ordinary sprays. Burgundy mixture gave slightly greater freedom from blight than Bordeaux mixture, but a somewhat lighter yield of tubers. It is considered better to spray several times at comparatively short intervals with a relatively weak mixture than a few times with a strong one. The names and relative ranks of varieties tested for resistance are detailed. Outbreaks appear to originate only from the planting of diseased potato tubers in which the fungus lives over from one season to the next.

Stalk, or Sclerotium, disease (*Sclerotinia sclerotiorum*) was less severe than in any of the five or six previous seasons. Infection occurs first on one or more of the older, yellowing leaves and then passes directly to the stalk. Abnormally early planting, in some localities, is thought to favor the disease. Two sprayings with lime-sulphur or with milk of lime decreased the attack and increased the yield. Attention is called to recent findings that this fungus has no Botrytis stage, as formerly held.

Botrytis cinerea was studied under favorable conditions as it developed, unmasked by blight, in July and the early part of August, and its characters, habits, and effects are detailed. It is regarded as not definitely proved that B. cinerea is the conidial stage of S. fuckeliana. The usual sprays have little or no effect upon this disease, but it is resisted by the same varieties which are resistant to blight.

Verticillium alboatrum has thus far been observed at three places in Ireland. It spreads from the infected mother tubers into the young stalks, and practically any part of the plant, if left, will contaminate the soil. Heating tubers for five hours from 41 to 45.5° C. does not kill the fungus nor does it injure the tubers.

Hypochnus (Rhizoctonia) solani was studied, and it is concluded that under the conditions employed this fungus does not cause a rot of potato tubers.

Work has been done with other diseases, some of which is still incomplete. Notes given in this connection refer to Spongospora subterranea, Spondylocladium atrovirens, Fusarium caruleum, and P. erythroseptica.

Cork, drought spot, and related diseases of the apple, A. J. Mix (New York State Sta. Bul. 426 (1916), pp. 473-522, pls. 12; abs., pp. 8, figs. 9).—A description is given of two little known diseases which were observed in the Champlain Valley, New York. Both are nonparasitic in nature and may be different types of the same disease. They are considered closely related to the well-known fruit pit or stippen disease. The names drought spot and cork are proposed for them. Associated with the drought spot are abnormal conditions of the twigs

and foliage, and it is proposed that these be designated drought dieback and drought rosette.

Cork is said to affect chiefly the Fameuse variety. In addition to occurring in New York, it is also known to be present in Ontario and New South Wales. The drought spot has been reported from Maine and Virginia, while a closely related trouble is said to occur in the Pacific Northwest. Rosette has been reported from Colorado, California, and Idaho, and both rosette and dieback occur in the irrigated sections of Washington and Oregon. It is claimed that in the Champlain Valley certain orchards and even individual trees are more affected than others.

In infected trees, cork is evident late in June as dead brown spots beneath the skin of the fruit or around the core. Later the fruit becomes distorted and knobby, and brown corky spots are said to occur throughout the flesh. Drought spot occurs in early June and fresh stages may develop throughout the summer if the weather continues dry. Superficial or sunken dead brown spots show in the skin of the fruit and dead brown areas may occur in the flesh beneath. In later stages, the apples become cracked and deformed. The internal spots of both diseases are in close proximity to branches of the vascular system.

Die-back associated with drought spot is characterized by the death of the twigs from the tips backward. The dead twig may be replaced by a healthy lateral from the base, but often there is found near the base of the twig a rosette-like cluster of dwarfed leaves. This appearance and one in which a compact cluster of similarly dwarfed leaves crowns a long, bare twig have been included under the name rosette.

From field observations it appears that these diseases may occur on the best types of soil and under conditions of careful culture. Poor moisture supply seems to be connected with their occurrence, and a drought accompanied by high, dry winds appears to bring on a large amount of the diseases. It is said that these troubles may appear to a limited extent in a rainy season when lack of moisture can not be considered their sole cause. This is believed, however, to be the predisposing factor, though other as yet unknown factors may be operative.

Conservation of soil moisture and even distribution of moisture throughout the season are thought to be the only satisfactory methods of control.

Rhizopus rot of strawberries in transit, N. E. Stevens and R. B. Wilcox (U. S. Dept. Agr. Bul. 531 (1917), pp. 22, fig. 1).—In continuation of previous investigations (E. S. R., 35, p. 458), the authors give an account of field and laboratory studies of the rot of strawberries due to R. nigricans, with special reference to the relation of the disease to packing house and shipping problems. This fungus is said to cause serious deterioration of strawberries during transit, the fruit softening and collapsing with the liberation of much juice, but it has not been found of primary importance as a cause of field rot, as it usually develops in the berries some time after they are picked. Conditions of shipping have been found to influence the development of the disease, the growth of the fungus increasing rapidly at temperatures above 50° F.

In some packing houses the berries are washed; and if they are packed without drying, the evaporation of the water, by cooling the berries, seems to retard the development of rot; but if they are dried before packing, especially by exposure to direct sunlight, the amount of decay is usually greatly increased. It is believed that proper cooling and refrigeration of the berries from the time they are picked until they are marketed will reduce the losses from this rot.

The control of American gooseberry mildew by spraying, F. R. PETHER-BRIDGE and A. C. Cole (Jour. Bd. Agr. [London], 23 (1916), No. 8, pp. 750-

[Vol. 37

755).—Observations during recent years, on the fruit plantations of the eastern counties, have shown that American gooseberry mildew has been reduced, and in some places almost eradicated, by growers who have subjected their bushes to a thorough tipping (cutting off and burning the diseased shoots), followed by two or three thorough sprayings with lime-sulphur during the growing season. The authors therefore undertook these experiments to ascertain how much the disease could be reduced in a single season by spraying alone, employing for this purpose the variety Whinham Industry, on the plats used by Brooks, Petherbridge, and Spinks, as previously noted (E. S. R., 34, p. 846). The hand pumps used gave a pressure of 60 lbs. per square inch and carried swivel nozzles set to spray almost vertically.

The results show that 2.5 per cent lime-sulphur is, in certain seasons, capable of reducing the American gooseberry mildew attack on the berries to less than 1 per cent even in case of a susceptible variety badly affected previously. The first spraying should be applied before the primary outbreak in the spring, preferably the first week in April. Two more sprayings, three or four weeks apart, should also be given. In 1916, the first week in May proved to be the most suitable time for a single spraying.

Thorough spraying reduces to a marked extent the disease on the shoots. Tipping, as carried out commercially, is of little value on a thoroughly infested plantation in such a season as the one in question.

Mysterious vine disease, J. W. Jeffrey (Mo. Bul. Com. Hort. Cal., 5 (1916), No. 11, pp. 416, 417).—A peculiar grapevine trouble has appeared in several districts of California for each of the last three seasons. The vines start with apparently normal vigor in spring but lose their leaves in midsummer, and show later only a small, sickly leaf at each axil, the fruit meanwhile withering away in an immature condition. Although weakened the second season, the vines may not die until the third season. No variety is immune, so far as known. The trouble appears to be independent of soil and irrigation, though a decay of the roots seems to precede the final death of the plants.

The gray root fungus of cinchona, A. Rant (Bul. Jard. Bot. Buitenzorg, 2. ser., No. 22 (1916), pp. 23, pls. 3).—An account is given of observation and experimentation on a gray root fungus on cinchona, which has been observed to attack also a considerable number of other plants named. The organism, which appears to be transmitted through both soil and air, is considered as genetically related to Graphium.

Control of black spot and brown spot in citrus, G. P. DARNELL-SMITH (Agr. Gaz. N. S. Wales, 27 (1916), No. 12, p. 844).—Black spot (Phoma citricarpa) of oranges and brown spot (Colletotrichum glæosporioides) of oranges and mandarins have been dealt with during four years by O. Brooks at Erina, and the results are briefly set forth.

Of the spraying solutions tested, potassium sulphid and copper sulphate were dropped after the first year, and formalin and lime-sulphur after the third year, leaving Bordeaux mixture alone to be tested the fourth year. This preparation, at first used at a strength of 6 lbs. of copper sulphate with 4 lbs. of lime in 50 gals. of water, can, according to subsequent tests, be reduced to half that strength, or less, with complete safety. The lime should be freshly burnt and the mixture applied as soon as made, the application to be preceded by a thorough pruning of all dead or diseased wood.

Composition of citrus leaves at various stages of mottling, C. A. Jensen (U. S. Dept. Agr., Jour. Agr. Research, 9 (1917), No. 6, pp. 157-166).—In experiments carried on at the California Citrus substation at Riverside, the author undertook to determine whether mottled citrus leaves show a deficiency of the mineral elements directly affecting chlorophyll formation.

From a comparison of the average percentages of the inorganic elements in healthy leaves and leaves in medium stages of mottling, data were obtained which are considered not to show that the initial mottling could be accounted for by deficiency in the transfer of the iron, calcium, magnesium, and phosphoric acid from the conducting system of the leaf stem and midrib to the mesophyll tissue. On the other hand sharply localized yellow areas in old orange leaves contained less of these elements than the adjoining green areas, but whether this relation obtained in the initial stages of mottling was not determined. In very badly mottled leaves there was found in general an increase in the percentage of these elements in the conducting tissues, including the leaf stems, indicating difficulty in their transfer to the mesophyll tissues, probably because the leaf had become functionless.

Relation of nitrogen to mottle-leaf, I. G. McBeth (U. S. Dept. Agr., Jour. Agr. Research, 9 (1917), No. 7, pp. 248-250).—In investigations carried on by the author in cooperation with the California Citrus substation, Riverside, and noted on page 352, in which a study was made of factors influencing nitrification and the forces controlling the distribution of nitric nitrogen as related to the nutrition of citrus trees, much attention was given to the production and distribution of ammonia and nitrate and their possible relation to mottling, a serious trouble of oranges and other citrus trees. Mottled orange leaves were found to have a higher moisture content and in general a higher nitrogen content than healthy leaves of the same age from the same tree. Extreme mottling is frequently found associated with high nitrate content, but the correlation is said to be by no means an invariable one.

A new species of Endothia, S. C. Bruner (Mycologia, 8 (1916), No. 5, pp. 239-242, pl. 1).—An account is given of a study by the author of a fungus said to be common as a saprophyte or parasite on several species of Eucalyptus, and saprophytic on mango (Mangifera indica), in the vicinity of Santiago, Cuba. The fungus is an Endothia, somewhat resembling E. radicalis, but as a result of studies by the author it is considered as a new species and has received the name E. havanensis. The pycnidial stage has been observed on Persea gratissima and Spondias mombin. The fungus is thought to be of Cuban origin.

Rose diseases, L. M. Massey (Amer. Florist, 47 (1916), No. 1489, pp. 1148, 1149).—An extensive investigation of rose diseases was undertaken in 1916 by the department of plant pathology of Cornell University in connection with the American Rose Society. The preliminary survey shows that on both indoor and outdoor plants, powdery mildew and black spot are more common than other diseases, and the results of studies on these troubles are to be published later. Two varieties are affected with a root or crown rot, which is described. Other rose diseases are crown gall, Phyllosticta leaf spot, besides other leaf spots, and cane diseases of unknown causation.

A disease of Clivia under glass, G. Arnaud (Bul. Soc. Path. Veg. France 1 (1914), No. 1, pp. 36, 37, fig. 1).—A disease of Clivia in the greenhouse is described as due to the fungus Colletotrichum cliviæ.

An Alternaria on Sonchus, J. A. Elliott (Bot. Gaz., 62 (1916), No. 5, pp. 414-416, fig. 1).—A fungus said to cause a spot on leaves of S. asper, near Madison, Wis., and also on Lactuca canadensis, is reported as having been sent in by J. J. Davis, who has described the fungus as a new species under the name A. sonchi.

[Cucurbitaria pithyophila on Scotch pine in Scotland], C. M'Intosh (Trans. Roy. Scot. Arbor. Soc., 29 (1915), pt. 2, pp. 209, 210; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 11, pp. 1539, 1540).—A fungus parasitic on stems and branches of Scotch pine, noted near

Inver in 1907 and elsewhere later, attacking trees from 30 to 40 years old or older, has recently been found in a considerable number of felled trees, the fruiting body being present in many instances. The affected trees are suspected to have been grown from foreign seed.

The parasite may girdle and kill the branch, around which may form a fascicle of twigs resembling a witches' broom, or it may form a patch on one side, resulting in swellings and contortions and flooding the wood with resin. The effects are said to resemble those produced by *Peridermium pini corticola* (*Cronartium sp.*).

The canker of the Scotch pine caused by Dasyscypha subtilissima, A. W. Borthwick and M. Wilson (Trans. Roy. Scot. Arbor. Soc., 29 (1915), pt. 2, pp. 184-187, pl. 1; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 11, pp. 1540, 1541).—An account is given of observations made on a cankerous affection of Scotch pine as noted in the case of a specimen sent from Carmichael, in Lanarkshire. The fungus D. subtilissima, which has been previously known elsewhere as a saprophyte on P. sylvestris, is compared with D. willkommii, which it resembles in some respects, notably in the cankers produced (in case of the latter fungus, on larch). D. subtilissima is known to occur on several host species, and may be able to pass from one to the other. Experiments have been instituted to determine whether the larch can be infected by the fungus from the Scotch pine.

The acial stage of Coleosporium ribicola, W. H. Long (Mycologia, 8 (1916), No. 6, pp. 309-311).—The author has found a Peridermium on needles of piñon (Pinus edulis) near which Ribes leptanthum was growing, and has successfully inoculated the latter with aciospores of the fungus. He obtained a Coleosporium which proved to be identical in all its characters with C. ribicola. This is considered to prove that the fungus on piñon is the acial stage of C. ribicola and that it should be called P. ribicola, a technical description thereof being given.

The fungus is found early in the spring at an elevation of about 7,500 ft. The coleosporial stage occurs also at much lower elevations on Ribes, supposedly reaching these points by successive infection of Ribes plants throughout the summer months by the urediniospores.

Dothichiza populea in the United States, G. G. Hedgecock and N. R. Hunt (Mycologia, 8 (1916), No. 6, pp. 300-308, pls. 2).—Many reports having been received during the spring of 1916 of a serious blight of newly transplanted black populars (Populus nigra) and Canada populars (P. deltoides), a study was made of a fungus found, usually alone, in connection therewith. This proved to be morphologically identical with D. populea.

From earlier accounts it appears that this fungus has been imported, though not very recently, from Europe. The parasite attacks the trunk, limbs, and twigs of both of these poplars, causing cankers primarily. Trees, after becoming well established in the soil, may show marked resistance to the fungus. The fungus spreads most rapidly in trees recently transplanted or in those heeled in for early spring planting, but transplanted trees may become badly diseased from fresh infections between October and the following May.

D. populea is said to be the most rapidly growing of the canker-producing fungi known to the authors. Pycnospores spread the disease to adjacent trees, being carried by the wind, and perhaps also, while in the sticky stage or condition, by insects or birds. Eradication of diseased stock is the only control measure recommended.

# ECONOMIC ZOOLOGY-ENTOMOLOGY.

The parasites of food animals transmissible to man, B. H. RANSOM (Ann. Rpt. Proc. Missouri Valley Pub. Health Assoc., 1 (1915), pp. 45-49).—An address given in September, 1915, at the annual meeting of the Missouri Valley Public Health Association.

Concerning the pocket gopher and destructive habits, T. H. Scheffer (Better Fruit, 10 (1916), No. 10, pp. 7, 8, figs. 5).

A new monostome trematode parasitic in the muskrat, with a key to the parasites of the American muskrat, F. D. Barker (*Trans. Amer. Micros. Soc.*, 35 (1916), No. 3, pp. 175-184, pl. 1).—The author describes a small monostone trematode taken in large numbers from the intestine of an American muskrat from Lake Chisago, Minn., which represents the new genus and species *Nudacotyle novicia*.

Belle Fourche reservoir as a bird reservation and refuge for migratory waterfowl, F. M. DILLE (*Reclam. Rec.* [U. S.], 7 (1916), No. 6, pp. 267-269, figs. 2).—This description of the reservation includes a discussion of fall and spring migration, with notes on some conspicuous birds.

The Salt River national bird reservation, Arizona, G. Willett (Reclam. Rec. [U. S.], 7 (1916), No. 7, pp. 315, 316, figs. 2).—A brief description of this reservation, including a list of the fowl which frequent it.

East Park bird reservation, California, G. Willett (Reclam. Rec. [U. S.], 8 (1917), No. 1, pp. 33, 34, fig. 1).—A brief description of this reservation, with notes on the birds, made during the course of two visits, one in April, 1914, and the other in March, 1915.

The Deer Flat national bird reservation, Idaho, T. S. Palmer (*Reclam. Rec. U. S.*], 7 (1916), No. 5, pp. 221-223, fig. 1).—This description of the reservation includes an account of the location, birds on the reservation, how the birds are protected, and the opportunity for development.

The Minidoka national bird reservation, Idaho, F. M. Dille (Reclam. Rec. [U. S.], 7 (1916), No. 12, pp. 564, 565, figs. 3).—A brief description of the bird reservation adjoining the reservoir on the Minidoka project.

The birds of Culebra Island, Porto Rico, A. Wetmore (Auk, 34 (1917), No. 1, pp. 51-62).—This paper, which is based upon observations on Culebra Island from April 4 to 22, includes a discussion of the physical features, general conditions, and bird life on the island, together with a list of 14 species of birds observed on Louis Peña Island on April 11, and of 19 forms observed on Culebrita Island on April 15. The greater part of the paper is taken up by an annotated list of 54 forms of birds found on Culebra Island. Some of the data are included in the paper previously noted (E. S. R., 35, p. 155).

How birds' stomachs are examined, W. L. McAtee (Bul. Amer. Game Protec. Assoc., 6 (1917), No. 1, pp. 3, 4, figs. 4).

The technique of experimentation in agricultural entomology.—I, Thermostats and hygrographs, I. V. EMELIANOV (Kharkov. Oblast. Selsk. Khoz. Opytn. Sta., Ent. Otd., No. 1 (1915), pp. 55, figs. 22).—This first paper discusses methods of determination of temperature and moisture.

The longevity of some insects in captivity, A. LABITTE (Bul. Mus. Nat. Hist. Nat. [Paris], No. 2 (1916), pp. 105-113; abs. in Rev. Appl. Ent., Ser. A, 5 (1917), No. 1, pp. 20, 21).—This paper, which relates to the Coleoptera, records observations made of the average length of life in days of both sexes of 50 forms and the maximum period of existence of 48 species.

Precipitation in relation to insect prevalence and distribution, N. CRIDDLE (Canad. Ent., 49 (1917), No. 3, pp. 77-80).—In this paper the author calls

attention to a few instances in which humidity, chiefly in the form of rain or snow, has been and is instrumental in either aiding or curtailing the spread of insects over the country, particularly in the prairie Provinces of Canada.

Investigations on the resistance of the larvæ of Cossus and Carpocapsa to cold, MLLE. F. GUEYLARD and P. PORTIER (Compt. Rend. Soc. Biol. [Paris], 79 (1916), No. 15, pp. 774-777).—The authors conclude that the larva of Cossus cossus is able to resist a complete freezing of all its organs and tissues and that freezing may be repeated a considerable number of times without its tissues being altered. A rapid rise of temperature, from —15° to 30° C., (from 5° to 86° F.), did not cause the death of the caterpillar or appear to alter its tissues. This resistance to cold results from an adaptation during the winter months only.

The reactions of the larva of the codling moth appear to be quite similar.

The insects attacking stored wheat in the Punjab, and the methods of combating them, including a chapter on the chemistry of respiration, J. H. Barnes and A. J. Grove (Mem. Dept. Agr. India, Chem. Ser., 4 (1916), No. 6, pp. VI+165-284, pls. 5, figs. 12; abs. in Ent. Mo. Mag., 3. ser., 3 (1917), No. 28, pp. 88-90).—The several chapters of this memoir, based upon investigations first commenced in 1911, deal, respectively, with the life history of the principal insects infesting wheat in the Punjab, chemical experiments, respiration, effect of moisture and dryness on the rice weevil, Attagenus undulatus, and Rhizopertha dominica.

The insects found in stored wheat consist of eight species of Coleoptera and one of Lepidoptera. Only three of these are actively responsible for damage to the wheat, namely, the dermestid A. undulatus, the bostrychid R. dominica, and the rice weevil. Of the other species, Læmophloeus sp. is found only ou floury frass and grains already damaged by other insects. Tribolium castaneum was proved by experiment unable to live on sound grains, and is strictly a flour beetle rather than a wheat beetle, as is Latheticus oryzae. Alphitobius piceus appears to be merely a scavenger and not to attack the grain, and the granary weevil is rarely found. The Angoumois grain moth was observed in only one district. The life histories of these insects are dealt with and illustrated in colored plates.

The senior author is largely responsible for the chemical and physical studies and the mechanical and remedial work and the junior author for the entomological phases.

Florida truck and garden insects, J. R. Watson (Florida Sta. Bul. 134 (1917), pp. 35-127, figs. 57).—This is a summary of information in which particular attention is given to control measures.

Insects injurious to timber in Sweden, N. A. Kemner (Meddel. Centralanst. Försöksv. Jordbruksområdet, No. 108 (1915), pp. 45, figs. 33; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 3, pp. 465, 466).—The insects that are particularly injurious to timber in Sweden belong to the family Anoblidæ. A list is given of their important natural enemies and recommendations as to control measures.

Report of first expedition to South America, 1913, R. P. Strong, E. E. Tyzer, C. T. Brues, A. W. Sellards, and J. C. Gastiaburu (Cambridge: Harvard School Trop. Med., 1915, pp. XIV+220, pls. 49, figs. 9).—The main part of this work relates to Oroya fever and to verruga peruviana, which the authors consider to be separate diseases. The investigations of Townsend on insect transmission of verruga peruviana, previously noted (E. S. R., 35, p. 258), are also discussed. Chapters on entomological investigations at Matucana; uta; sanitary conditions, prevailing diseases, and entomological investigations.

gations at Guayaquil; investigations of the blood and clinical and pathological studies of yellow fever; and Linguatulida from crocodiles follow.

Papers on A New Linguatulid from Ecuador, by W. M. Wheeler; Some Flies of the Family Phoridæ Obtained by the Expedition, with Notes on a Species Possibly Associated with External Mylasis in Man, by C. T. Brues; Notes on Peruvian Mosquitoes and Mosquito Literature, by F. Knab; Heteroptera from the West Coast of South America, by J. R. de la Torre Bueno; and a list of the bees obtained by the expedition, by T. D. A. Cockerell, are appended to the report.

Report of the Kansas State Entomological Commission for 1915 and 1916 (Rpt. Kans. State Ent. Com., 1915-16, pp. 15).—This report consists of two parts. The first by G. A. Dean covers inspection of nurseries and imported nursery stock, work with the San José scale, and the location and suppression of foul brood in the north half of the State. The second part, by S. J. Hunter, deals with nursery, Federal, and apiary inspection and work with the San José scale in the south half of the State.

Annual report of work done in the entomological section during the year ended June 30, 1916, H. L. Durt (*Rpt. Dept. Agr. Bihar and Orissa*, 1915-16, pp. 10-12).—This reports upon the occurrence of the more important insect pests of the year.

Reports of the microbiologist, H. M. Nicholls (Agr. and Stock Dept. Tasmania Rpt., 1913-14, pp. 28, 29; 1914-15, pp. 5, 6; 1915-16, pp. 18-20).—Brief accounts are given of the occurrence of the more important insect pests of the three years.

Notes on Argentine, Patagonian, and Cape Horn Muridæ, O. THOMAS (Ann. and Mag. Nat. Hist., 8. ser., 17 (1916), No. 98, pp. 182-187).—Five forms are described as new.

The sheep tick and its eradication by dipping, M. IMES (U. S. Dept. Agr., Farmers' Bul. 798 (1917), pp. 31, figs. 15).—An account is given of the life history and habits of the sheep tick or ked (Melophagus ovinus) and means for its control, in which it is pointed out that the only practical way of destroying it is by dipping the sheep. Two dippings about 25 days apart are necessary, since the first dipping may not destroy the eggs. Lime-sulphur-arsenic dip is said to be the most effective. Plans are given for wooden and cement sheep dipping vats.

The destruction of locusts in Colombia by dipterous parasites, M. T. Dawe (Rev. Agr. [Colombia], 2 (1916), No. 3, pp. 143-150; abs. in Rev. Appl. Ent., Ser. A, 4 (1916), No. 10, p. 410).—A brief account is given of two sarcophagids found to be parasitic on locusts (Schistocerca paranensis) at two localities in Colombia, namely, Sarcophaga caridei and a species of doubtful identity. The various methods used in combating locusts are reviewed, and a list is given of the locust parasites recorded from various parts of the world.

The cacao thrips, J. C. Hutson (Agr. News [Barbados], 16 (1917), No. 385, pp. 26, 27).—This is a brief general account of Heliothrips rubrocinctus, studied by the author during a recent visit to Grenada.

Mites and lice on poultry, F. C. BISHOPP and H. P. Wood (U. S. Dept. Agr., Farmers' Bul. 801 (1917), pp. 26, figs. 14).—This is a popular summary of information on the common mites and lice, in which particular consideration is given to means for their control.

A contribution to the study of kala-azar, J. W. Cornwall and H. M. La Frenais (Indian Jour. Med. Research, 3 (1916), No. 4, pp. 698-724, pls. 3; 4 (1916), No. 1, pp. 105-119, pl. 1).—The authors' provisional conclusions are that "Cimex rotundatus can not transmit either kala-azar or oriental sore by

biting. Viable forms of *Leishmania donovani* and *L. tropica* are not passed in the feces of *C. rotundatus*. *Conorhinus rubrofasciatus* is not concerned in the transmission of kala-azar."

Notes on a froghopper attacking sugar cane at Marienburg Estate, Surinam, C. B. WILLIAMS (Bul. Ent. Research, 7 (1917), No. 3, pp. 271, 272).—The author's observations indicate that Tomaspis tristis may become a serious pest of sugar cane in Surinam.

Aphids injurious to orchard fruits, currant, gooseberry, and grape, A. L. QUAINTANCE and A. C. BAKER (U. S. Dept. Agr., Farmers' Bul. 804 (1917), pp. 42, figs. 30).—A practical summary of information, including control measures.

The San José scale, F. B. PADDOCK (Texas Sta. Circ. 18 (1916), pp. 3-11, figs. 3).—A brief summary of information on the San José scale and its control.

Some new scale insects of Japan, S. I. Kuwana (Annot. Zool. Japonenses, 9 (1916), pt. 2, pp. 145-152, pl. 1).—One genus (Nipponorthezia) and seven species are described as new.

A scale enemy of the vine in Uruguay, G. Schurmann (Rev. Asoc. Rural Uruguay, 44 (1915), No. 8, pp. 481-483, fig. 1; abs. in Rev. Appl. Ent., Ser. A, 4 (1916), No. 8, p. 351).—Pulvinaria vitis appeared in Uruguay for the first time in 1914 and has become a source of serious injury to vineyards.

The introduction of Diaspis pentagona and its control in Argentina, A. Gallardo (An. Zool. Aplicada, 3 (1916), No. 1, pp. 33-50; abs. in Rev. Appl. Ent., Ser. A, 4 (1916), No. 11, p. 467).—A review of the history of the introduction of the West Indian peach scale into Argentina and its control there by Prospattella berlesei.

The pink bollworm, W. D. Hunter (Science, n. ser., 45 (1917), No. 1160, pp. 293, 294).—Following a brief reference to the occurrence of Gelechia gossypiella in Mexico and to the inspection work being carried on by the U. S. Department of Agriculture with a view to preventing its introduction into this country, the author records its recent introduction into Brazil in cotton seed from Egypt. It is stated that a careful survey of the cotton belt in Brazil early in 1914 failed to detect its presence there, although late in 1916 during another trip made over the same territory it was found generally and thoroughly established and so numerous that the yields of certain fields were reduced by 50 per cent.

The life of the caterpillar, J. H. Fabre, trans. by A. Teixeira de Mattos (New York: Dodd, Mead & Co., 1916, pp. 376).—This, the sixth volume of the collected edition of the author's entomological works (E. S. R., 35, p. 468) contains all his essays on butterflies and moths, or their caterpillars.

A few notes on the life history of Phalonia spartinana, C. N. AINSLIE (Canad. Ent., 49 (1917), No. 3, pp. 93-96, pl. 1).—The larva of this lepidopteran (P. spartinana) lives on Spartina michauxiana.

Recent questioning of the transmission of verruga by Phlebotomus, C. H. T. Townsend (Bul. Ent. Research, 6 (1916), No. 4, pp. 409-411).—The author here answers the objections raised by Strong et al. in their report noted on page 356.

It is pointed out that the author's conclusion that *P. verrucarum* is the vective agent of verruga is based upon nearly two years' experience with the blood-sucking fauna of the Rimac verruga zone in Peru. Papers relating to the subject by him have been previously noted (E. S. R., 35, p. 258).

Studies in flies.—Contributions to the study of specific differences in the genus Musca: II, Structures other than genitalia, P. R. Awati (Indian Jour. Med. Research, 4 (1916), No. 1, pp. 123-139, figs. 10).—This third paper (E. S. R., 35, p. 856) deals with structures of the head, thorax, and abdomen.

Two new genera of African Muscoidea, C. H. T. TOWNSEND (Ann. and Mag. Nat. Hist., 8. ser., 17 (1916), No. 98, pp. 174-176).—The genera Congochrysosoma and Ocypteromima, together with the genotype of each, are described as new.

The lantana seed fly, F. P. Jepson (Dept. Agr. Fiji Pamphlet 31 (1916), p. 1; abs. in Rev. Appl. Ent., Ser. A, 4 (1916), No. 12, p. 529).—An agromyzid introduced from Hawaii into Fiji is now so thoroughly established that it is not possible to find Lantana camara within several miles of Suva which is not attacked.

Plagiodera versicolora.—An imported poplar and willow pest, H. B. Weiss and E. L. Dickerson (Canad. Ent., 49 (1917), No. 3, pp. 104-109, pl. 1).—This imported chrysomelid has been observed by the authors in New Jersey for the past three years, appearing in greatest numbers at Irvington in a nursery on poplar and at South Paterson on willow. Observations relating to its biology are reported.

Scientific annihilation of the tobacco beetle, R. G. SKERRETT (Sci. Amer., 115 (1916), No. 15, pp. 319, 336, fig. 1; abs. in Rev. Appl. Ent., Ser. A, 5 (1917), No. 1, p. 3).—A description of an X-ray apparatus made practical use of in the destruction of the cigarette beetle, an account of which by Runner has been previously noted (E. S. R., 35, p. 554).

Report of the South Carolina Boll Weevil Commission, W. M. Riggs (Clemson Agr. Col. S. C., Farmers' Reading Course Bul. 20 [1916], pp. 24, figs. 2; U. S. Senate 64. Cong., 2. Sess., Doc. 701 (1917), pp. 20, figs. 2).—This is a report of a commission which made a trip of inspection through the boll-weevil infested territory. It includes a report of a meeting held at Brookhaven, Miss., on October 7, 1916, a brief account of the life history of the boll weevil, a comparison of the conditions in Louisiana and South Carolina as related to the boll-weevil problem in the latter State, effects of the boll weevil on cotton production, oil mills, ginneries, etc., changes in agricultural methods due to the boll weevil, and raising cotton under boll-weevil conditions.

On some Curculionidæ which live in bamboo stems, A. DA COSTA LIMA (Mem. Inst. Oswaldo Cruz, 8 (1916), No. 1, pp. 41-43).—This supplementary paper (E. S. R., 33, p. 658) refers to Rhinastus pertusus in Chusquea gaudichaudii, Desmosomus longipes, and Astyage punctulata n. sp., in Mcrostachys clausseni mollior.

The leaf weevil (Polydrusus impressifrons), P. J. Parrott and H. Glasgow (New York State Sta. Tech. Bul. 56 (1916), pp. 3-24, pls. 8, figs. 6).—P. impressifrons, an important European bud and leaf-eating beetle of which a preliminary account has been noted (E. S. R., 36, p. 859), was first discovered in western New York in 1906, where it occurs in several counties and in certain localities has become very abundant, particularly in nurseries. It feeds on a large variety of plants, particularly upon willows, poplars, and birches. It is a source of injury through nibbling the developing buds of budded and grafted stock and attacking the foliage and succulent tissues, as stems of newly-unfolded leaves and stalks of terminal growth. The gouging of tender tissues is not infrequently attended by severing of leaves and destruction of tips of shoots.

The adults, which are light metallic green in color, emerge from the ground during May and early June and oviposition soon commences. The eggs are deposited under the loosened bark on dead stubs or about wounds due to pruning or scars in the bark resulting from hail injury or attacks by insects, and hatch in about 11 or 12 days. Upon hatching out the larvæ enter the earth and live on the roots of plants. Pupation occurs in the spring.

A new braconid of the genus Diospilus, a description of which by A. B. Gahan under the name *Diospilus polydrusi* is appended (pp. 23, 24), has been

quite abundant and during recent years apparently has been exerting an important repressive action on its host. Protection from the beetle can be obtained through the use of arsenicals at standard strengths.

Bees for the farmer, J. Troop and W. A. PRICE (Indiana Sta. Circ. 61 (1917), pp. 20, figs. 10).—This is a popular summary of information for the beekeeper.

Outdoor wintering [of bees], E. F. PHILLIPS (Iowa Yearbook Agr., 16 (1915), pp. 564-572).—Substantially noted from another source (E. S. R., 34, p. 158).

The sense organs on the mouth parts of the honeybee, N. E. McIndoo (Smithsn. Misc. Collect., 65 (1916), No. 14, pp. 55, figs. 10).

Contribution to the etiology of infectious diarrhea of bees caused by Bacterium coli apium n. sp. and Proteus alveicola n. sp., I. L. Serbinov (Zhur. Mikrobiol., 2 (1915), No. 1-2, pp. 19-44, pls. 2, fig. 1).—The author describes a new form of diarrhea which has occurred in the spring for a number of years among bees on the south coast of the Gulf of Finland, near Oranienbaum. Two new bacteria considered to be causative organisms of the disease are described. The disease develops rapidly and becomes epidemic, the bees become weakened, and death follows frequently in convulsions.

The connection of Nosema apis with Isle of Wight disease in hive bees.—Remarks on the evidence submitted in the Board of Agriculture reports of 1912 and 1913, J. Anderson (Proc. Roy. Phys. Soc., Edinburgh, 20 (1916), No. 1, pp. 16-22; abs. in Rev. Appl. Ent., Ser. A, 4 (1916), No. 11, p. 462).—The author's observations do not entirely support the view that N. apis is the cause of Isle of Wight disease.

Observations and experiments bearing on Isle of Wight disease in hive bees, J. Anderson and J. Rennie (Proc. Roy. Phys. Soc., Edinburgh, 20 (1916), No. 1, pp. 23-61, pl. 1; abs. in Rev. Appl. Ent., Ser. A, 4 (1916), No. 11, pp. 462, 463).—The observations here reported support those above noted.

Three new chalcid flies from California, A. A. GIBAULT (Jour. Ent. and Zool., 8 (1916), No. 3, pp. 119-122).

Monograph of the nearctic Hymenoptera of the genus Bracon, H. Morrison (*Proc. U. S. Nat. Museum*, 52 (1917), pp. 305-343, pls. 4).—The author recognizes 12 forms, of which 9 are described as new.

Signiphora merceti n. sp., E. Malenotti (Redia, 12 (1916), No. 1, pp. 181, 182; abs. in Rev. Appl. Ent., Ser. A, 4 (1916), No. 11, p. 483).—This new chalcidid was reared from Chrysomphalus dictyospermi in Spain.

Gonatocerus mexicanus, a mymarid parasitic in the eggs of Draeculacephala mollipes in Hawaii, O. H. Swezer (*Proc. Hawaii. Ent. Soc. 3* (1915), No. 3, p. 146).—This is said to be the first record of the establishment of G. mexicanus in Hawaii, the introduction of which from Chapultepec, Mex., was attempted by Koebele in 1908 (E. S. R., 27, p. 554).

The ticks which attack domestic animals in Russian Turkestan, W. L. Yakimoff (Bul. Soc. Path. Exot., 10 (1917), No. 4, pp. 298-301).—A summary of information relating to the Ixodidæ infesting domestic animals in Russian Turkestan.

Parasitism of Rhipicephalus sanguineus in Rio Janeiro by Hunterellus hookeri, A. da Costa Lima (Rev. Vet. e Zootech., 5 (1915), No. 4, pp. 201-203, pl. 1).—The author records the parasitism of nymphs of the brown dog tick by H. hookeri in Brazil.

On the occurrence of the tropical fowl mite (Liponyssus bursa) in Australia, and a new instance of its attacking man, S. Hirst (Ann. and Mag. Nat. Hist., 8. ser., 18 (1916), No. 104, pp. 243, 244).—A widely distributed gamasid mite parasitic on domestic fowl, previously described by the author as Leiognathus morsitans (E. S. R., 35, p. 263), is now thought to be the same species as that described by Berlese, from specimens collected at Buenos Aires,

under the name *Liponyssus bursa*. Another instance of its attack upon man is recorded. The author suggests that the wide distribution of *L. bursa* may be due to its being carried about by the starling.

It is stated that the European fowl mite ( $Dermanyssus\ gallin\alpha$ ) apparently does not thrive in tropical and subtropical countries.

Contributions to the study of parasitic protozoa.—I, On the structure and life history of Nosema bombycis, R. Kudo (Bul. Imp. Sericult. Expt. Sta. Japan, 1 (1916), No. 1, pp. 31-51, pls. 2).—This first paper dealing with the structure and life history of the causative organism of pebrine in the silkworm includes a bibliography of 43 titles.

Contribution to the study of larval forms of heteroxenous nematode parasites, L. G. Seubar (Bul. Sci. France et Belg., 49 (1916), No. 4, pp. 297-377, figs. 14).—This paper, dealing with the Spiruridæ and Acuariidæ, includes a catalogue and a 12-page bibliography of the literature relating to the subject.

Two new cases of polyradiate cestodes, with a summary of the cases already known, W. D. Foster (Jour. Parasitology, 2 (1915), No. 1, pp. 7-19, figs. 4).—In reviewing the literature the author finds that altogether 44 cases of polyradiate cestodes, including larvæ, have been reported, in all but two of which the adult forms were triradiate. The fact that the greater number of these cases are triradiate forms of Tænia saginata, although several species are represented, is thought to be due to the greater chances for observation of this species.

A feeding experiment with triradiate proglottids of *T. pisiformis* tended to show that in this species perfectly normal cysticerci may result from abnormal adults.

Polyradiate cestodes, F. D. BARKER (Science, n. ser., 43 (1916), No. 1101, pp. 170, 171).—The author calls attention to a paper which gives descriptions of two new species of polyradiate cestodes not referred to in the paper above noted. It was based upon a study of four perfect and entire specimens of Tania serrata, i. e., T. pisiformis, and three perfect specimens of T. serialis from dogs at Lincoln, Nebr.

A further note on polyradiate cestodes, W. D. Foster (Science, n. ser., 44 (1916), No. 1133, pp. 388, 389).—A further discussion of the subject in which the author replies to the paper above noted.

## FOODS—HUMAN NUTRITION.

Characteristics and quality of Montana-grown wheat, L. M. Thomas (U. S. Dept. Agr. Bul. 522 (1917), pp. 34, pls. 2, figs. 17).—This bulletin contains information regarding the varieties and types of wheat grown in Montana and their grading, together with a discussion of wheat quality, color of flour and bread, water absorption, loaf volume, and texture. It also reports the results of a number of baking tests with Montana wheat and gives data regarding the correlation of physical characters and milling quality and a comparison of the wheats of Montana with those grown in other sections.

In conclusion the author states that five distinct classes of wheat are produced in Montana, which may be designated as hard spring, hard winter, western red, western white, and durum. "The two first-named classes are of about the same milling quality, except that the spring wheat is decidedly superior to baking strength. The wheats of these two classes also resemble each other closely in physical characteristics and composition; both are best suited for the production of a bread flour.

<sup>&</sup>lt;sup>1</sup> Science, n. ser., 31 (1910), No. 804, p. 837.

"The flour from the western red and western white wheat is very low in strength and absorption and has the general characteristics of other soft-wheat flours. The flour is best adapted for the production of crackers and pastry products. The bread produced from this wheat is very close-textured and heavy.

"Durum wheat is decidedly different from the wheat of any other class. Although generally yielding a high percentage of flour, the flour is usually very creamy or yellow in color and consequently receives a low score for color. In spite of the fact that the flour contains a very high percentage of crude protein, it falls between the hard winter and western red wheats in baking strength. In water absorption the flour is slightly superior to that of all other classes. The flour from this wheat is not popular for bread-making purposes on account of its creamy color, but it is especially adapted for the manufacture of macaroni and similar products."

A table is given showing the average of results of all baking tests of each of the five classes of Montana wheat.

The capacity of wheat and mill products for moisture, W. L. STOCKHAM (North Dakota Sta. Bul. 120 (1917), pp. 97-181, figs. 12).—This bulletin reports the results of an extended study of the absorption of water vapor and water in the liquid state by wheat and wheat products. The results of the study may be summarized as follows:

"The capacity or amount of water required to make a mixture of a given consistency of water and colloidal material is greatest when the component parts are in a state of equilibrium with each other.

"The capacity of wheat and its products for atmospheric moisture and water increases as the physical equilibrium between the component particles is approached. Wheat has a higher moisture capacity than any of its products. . . . Starch prepared from patent flour has a higher capacity for atmospheric moisture than that from clear flour.

"The capacity of wheat for atmospheric moisture is greater at 0° C. than at higher temperatures, diminishing with increase in temperature. Above 60° it is dependent upon chemical changes which in turn are dependent upon the amount of moisture available. With the humidity zero the capacity is zero regardless of the temperature. At the saturation point between 0 and 40° C. the theoretical limits are only one-third to one-half reached because of secondary changes produced by enzyms, bacteria, and molds.

"Previously sprouted wheat absorbs both water and water vapor more rapidly than wheat in the natural state. It reaches its maximum sooner but does not reach as high a maximum as the normal wheat. Wheat products have a more rapid rate of adjustment to modified moisture conditions than wheat and are more subject to secondary changes.

"Germination does not take place from water absorbed from the atmosphere (condensation excluded).

"The rate of change of the moisture content of wheat in the atmosphere or in water becomes slower as the maximum limits are approached. . . .

"The absorptive capacity of the wheat varies inversely as the water-absorbing power of the flour produced from the same wheat, and as a rule inversely to the protein content. The durums are similar to hard red spring wheat samples of the same protein content in rate and quantity of water absorbed. . . . The absorptive capacity varies with the protein content of flours of the same grade. This relation is not so marked between different flour grades. . . .

"Sprouted wheat flour has on the average a 2 per cent lower absorption than that from the same wheat in the natural state. Both normal and sprouted

wheat flour increase in absorptive capacity during storage; in some instances as much as 3 or 4 per cent. . . .

"The proportion of water in gluten is slightly higher under conditions which give it the greatest freedom during its formation, i. e., with higher temperature, or with more water at its disposal. Approximately 180 per cent of water is absorbed by gluten, and once it is formed it retains practically a constant amount of water at all temperatures below its decomposing point.

"The absorption of a starch gluten mixture is less than the sum of the absorption of the two taken separately.

"By hydrolysis starch has its capacity for water doubled. By dextrinization it is markedly decreased.

"By baking or by decomposition gluten has its capacity for water decreased. Baked gluten does not vary in water capacity with change in temperature.

"The maximum staleness of bread occurs when the ratio of water present in the bread to the capacity of the starch is least, or the fresher the bread the more nearly satisfied with water are its starch particles, and with a given moisture content this satisfaction would vary with the temperature changes inversely as the absorptive capacity of either starch, hydrolyzed starch, or bread.

"The capacity for moisture of the inner portion of the bread indicates that practically all of the starch is hydrolyzed during the baking process. That of the crust is less, indicating some dextrinization.

"The higher the starch content of a flour the more water would it require in proportion to its capacity to produce a loaf of a given apparent freshness."

The composition of rice and its by-products, G. S. Fraps (Texas Sta. Bul. 191 (1916), pp. 41).—This bulletin reports the analysis of different varieties of rice and the various intermediate products of milling and discusses the composition, food, and feeding value of rice and rice by-products. A description is also given of the milling process. From the data here reported the following conclusions are drawn:

Milling rice gives it a whiter and more attractive appearance and partly removes phosphoric acid, potash, vitamins, and other constituents. White or milled rice has a different taste and better cooking quality than does the unmilled or brown rice.

"Chicken feed, or rough rice screenings, contains chiefly weed seeds, broken rice, and dirt, and is variable in composition. So-called stone bran is the sifting from rice hulls and rice and consists largely of rice hulls, with some rice bran, germ, and broken rice. Stone bran from Blue Rose rice contains more fat and more fiber on an average than that from Honduras rice. Rice hulls also get into rice bran with the so-called chits. Huller bran, or rice bran removed by the huller, is rich in protein and fat and is practically free from hulls. Rice hulls have a very low feeding value, but there is no evidence that they are actually poisonous or injurious to animals.

"The rice bran on the market consists of a mixture of huller bran, cone bran, and stone bran. The addition of hulls, immature rice, inferior stone bran, excessive amounts of stone bran, chicken feed, dust, or any other milling by-product, is an adulteration."

Tables are given showing the composition and feeding value of rice bran and rice polish. These two products compare favorably with corn. A method is also given for calculating the hull content of rice from the fiber content. The author states that the production coefficients of rice by-products vary with the grade, as does the productive value and the digestible protein.

Rice bran and rice huller bran contain large percentages of fat, but the extraction of this fat commercially has not been successful. A table is given showing the mineral and sugar contents of rice and its by-products.

"Dust from rough rice contains much dirt and hulls, and its presence in a feed is highly objectionable. Light rice consists chiefly of hulls, and the addition of light rice or the grindings from it to rice bran is an adulteration. Rice hull ashes consist mostly of silica and have an average fertilizer valuation of \$1.38 per ton."

Experiments in the determination of the digestibility of millets, C. F. LANGWORTHY and A. D. Holmes (U. S. Dept. Agr. Bul. 525 (1917), pp. 11).— This paper reports the results of a study of the digestibility of common millet (Setaria italica) and proso (Panicum miliaceum). The methods employed in this investigation were similar to those used in an earlier study of the digestibility of the grain sorghums (E. S. R., 36, p. 660).

The millets were eaten in the form of a bread, which was added to a basal ration low in protein and consisting of potato, orange, and sugar. Five normal young men served as the subjects of the experiment. Since millets do not contain gluten, they are not suitable for making leavened bread when used alone, but may be used for making unleavened bread and may be prepared for the table in ways similar to the grain sorghums and corn meal. The amount of the protein supplied by the ration averaged less than 50 gm. per day, due to the low protein content of the bread prepared from millets.

The breads made from bolted millet and proso meal did not show a high digestibility for protein in these experiments, the values being 35.8 per cent for millet protein and 41.2 per cent for proso protein.

No marked difference was noticed in the flavor of the millet and proso breads. A decorticated millet made into a mush was found to give a product of pleasing flavor, but a sufficient quantity was not obtained for a study of its digestibility.

The carbohydrates of millet and proso were found in these experiments to be as well utilized by the subjects as are those of the more common cereals, the coefficients of digestibility being 95.7 per cent for millet and 96.2 per cent for proso.

The general conclusion is drawn that "while the millets would contribute somewhat to the protein of the diet, they would be decidedly more important as a source of carbohydrates than of protein. In this they resemble such grains as the sorghums more closely than they do wheat or rye, which are important sources of both protein and carbohydrates."

Bread and bread making in the home, Caroline L. Hunt and Hannah L. Wessling (U. S. Dept. Agr., Farmers' Bul. 807 (1917), pp. 26, figs. 3).—This deals with the importance of bread in the diet, the qualities of good bread, and the principal requirements of bread making. Under the last head are included choice of materials and utensils; cleanliness; proportions of ingredients; measuring, mixing, and molding; and the care of the dough at various stages and care of the finished product. Recipes are given for making wheat bread by different methods, and for biscuits, rolls, and potato, wheat, rye, corn, and other breads. Suggestions for the judging of bread and a discussion of the food value of bread and its place in the diet are included.

Forty-three ways to save the wild plum crop, G. W. CARVER (Alabama Tuskegee Sta. Bul. 34 (1917), pp. 12).—A compilation of recipes.

How to select foods.—I, What the body needs, Caroline L. Hunt and Helen W. Atwater (U. S. Dept. Agr., Farmers' Bul. 808 (1917), pp. 14, figs. 2).—This is a popular statement of what the body needs to obtain from its food for tissue building, maintenance in good working order, and energy for its work. In general, it shows how different food materials meet these requirements and groups them according to their uses in the body, as follows: Foods depended on for mineral matters, vegetable acids, and body-regulating sub-

stances; for protein; for starch; for sugar; and for fat. One of the principles suggested for the planning of economical meals is that by remembering these groups and having them all suitably represented in the daily diet the house-keeper can easily plan attractive meals which meet the needs of the family without the wasting of money or material.

The effect of starvation on the catalase content of the tissues, W. E. Burge and A. J. Nelle (Amer. Jour. Physiol., 43 (1917), No. 1, pp. 58-61).—Data are submitted which show that during starvation the catalase content of the heart (rabbit) remains normally high, while that of the fat and skeletal muscles is greatly decreased.

From the results it is concluded that the heart is not autolyzed during starvation, "because oxidiation in this organ remains normally intense and thus provides for this oxidation of the autolyzing enzyms and the maintenance of the normal balance between oxidation and autolysis. On the other hand the fat and skeletal muscles are autolyzed during starvation, because of the decreased oxidation which leaves the autolytic enzyms free to digest these tissues."

# ANIMAL PRODUCTION.

Some commonly neglected factors underlying the stock breeding industry, R. Pearl (Maine Sta. Bul. 258 (1917), pp. 28, fig. 1).—In addition to an outline of the importance of the live-stock breeding industry as a business (E. S. R., 35, p. 772), the author discusses a number of factors which make for success in the business of breeding, including the test of progeny and its implications, continuity of purpose in breeding, the superiority of the pure bred, and the importance of the man himself in the successful breeding enterprise.

Steer feeding experiments, W. H. Tomhave, B. O. Severson, and P. Gerlaugh (Pennsylvania Sta. Bul. 145 (1917), pp. 3-20, figs. 3).—Summarized results are given of feeding experiments with steers conducted during the three winters 1913-14 to 1915-16, inclusive. The work of 1913-14 has already been noted (E. S. R., 32, p. 864). The six lots of 12 steers each were mostly two-year olds, and averaged about 900 lbs. at the beginning of the tests. The feeds used and some of the results secured during the two periods of 56 and 84 days, respectively, of each test are given in the following table:

Three-year summary of steer-feeding experiments.

	Period,	Average daily feed per steer.									gain	per n.	o pi	from
Lot.		Wheat bran.	Cottonseed meal.	Ear com.	Corn and cob meal.	Shelled corn.	Corn stover.	Corn silage.	Alfaifa hay.	Mixed hay.	Average daily per steer.	Dry matter pound of gain.	Cost per pound gain.	Average returns fr pork produced.

The authors interpret the results as indicating that "the common Pennsylvania ration of corn-and-cob meal, wheat bran, mixed hay, and corn stover, fed during the entire 140-day period, did not improve the finish nor value of the cattle, and it proved to be more expensive than any of the rations which contained silage as roughage only, or roughage and cottonseed meal in the early part of the feeding period, and whose combinations were supplemented with corn in the latter part; also when corn silage and cottonseed meal were fed during the entire period. Corn silage proved to be the most desirable roughage. A ration with a limited amount of corn silage supplemented with mixed hay was not so economical nor so satisfactory a roughage ration as one containing silage as a sole roughage. . . .

"A ration of corn silage and alfalfa hay as a source of protein during the first 56 days of the feeding period, supplemented with corn the balance of a 140-day period, was the cheapest daily ration, but it did not produce sufficient gains and finish.

"Wheat bran at \$25 per ton is not so desirable a source of protein as cottonseed meal at \$32.66 per ton, or alfalfa hay at \$15 per ton.

"The results from comparing alfalfa hay and cottonseed meal as a source of protein, in a ration of corn silage as roughage, supplemented with corn during the last three months of a five-month feeding period, indicate that cotton-seed meal is a superior source of protein on account of producing a more rapid finish on the cattle, which will thus command a higher selling price on the market.

"The margin necessary between the buying and selling prices is reduced by hogs following cattle in the feed lots, especially when whole grain is fed.

"Corn silage fed to the limit of appetite and supplemented with 2.5 lbs. of cottonseed meal per head daily the first three months, and 3.5 lbs. per head daily the last two months, proved to be the most economical ration. Cattle thus fed were valued within 5 cts. per 100 lbs. of cattle receiving, during the last 84 days, corn in addition to silage and cottonseed meal.

"The returns per steer, after paying for the feed consumed, were in direct proportion to the amount of silage consumed. The lots receiving the largest amount of silage alone and silage supplemented with cottonseed meal gave the best returns per steer.

"Five lbs. of alfalfa hay per day, in addition to 2.5 lbs. of cottonseed meal as a source of protein, was not found economical. . . .

"The manure produced was figured as being sufficient to pay for the bedding and labor required to take care of the cattle."

Feeding baby beeves, J. C. Burns (Texas Sta. Bul. 198 (1916), pp. 5-21. Ags. 8).—The objects of the experiments reported were to study the production of baby beef in general; to compare cottonseed meal, cold pressed cottonseed, and peanut meal for supplementing a ration composed of ground milo maize, corn, or sorghum silage, and Sudan grass hay; and to compare the feeding values of Sudan grass hay and cottonseed hulls.

Four lots of 12 high-grade Aberdeen-Angus steer calves were used. Before the experiment was begun the calves were fed together on a ration consisting of cold pressed cottonseed, ground milo maize, corn silage, and Sudan grass hay. In the experiment proper lot 1 was fed the above ration; lot 2, peanut meal, ground milo maize, corn silage, and Sudan grass hay; lot 3, cold pressed cottonseed, ground milo maize, corn silage, and Sudan grass hay; and lot 4, cottonseed meal, ground milo maize, corn silage, and cottonseed hulls. The actual feeding experiment covered a period of 201 days. Sorghum silage replaced corn silage for the last 51 days of the test and a small quantity of

blackstrap molasses was fed to all the lots as an appetizer for 11 days during the latter part of the experiment, the average daily allowance being 0.59 lb. per head. Pigs followed all lots.

At the close of the experiment very little difference in the gains of the four lots was observed, the average daily gains being 1.62, 1.52, 1.57, and 1.55 lbs. per head, respectively. Considerable advantage was found in having hogs follow the calves. The dressing percentages of the different lots of calves were practically the same, and little difference in the quality of carcasses was observed.

The calculations pertaining to the financial results of the experiment are based on the following costs per ton of the feeding stuffs used: Cottonseed meal, \$35; peanut meal (hulls included), \$28; cold pressed cottonseed, \$24; milo maize chops, \$23.80; corn silage, \$3.50; sorghum silage, \$3.50; Sudan grass hay, \$10; cottonseed hulls, \$10; blackstrap molasses, at 16.25 cts. a gallon, \$27. Based on the selling prices of \$9.50 per 100 lbs. for lots 1 and 3, \$9.41 for lot 2, and \$9.43 for lot 4, peanut meal (hulls included) was worth only \$21.40 per ton and cold pressed cottonseed only \$22.80 per ton, with cottonseed meal at \$35 per ton, while cottonseed hulls were worth only \$5.34 per ton with Sudan grass hay at \$10 per ton.

Detailed data are submitted in tabular form and discussed.

The production of baby beef, S. H. RAY (U. S. Dept. Agr., Farmers' Bul. 811 (1917), pp. 22, figs. 8).—This discusses the various phases of the production of baby beef for market, including the breeds and type of cows, bulls, and calves suitable for baby-beef production, the management and feeding of the breeding herd, calf management and feeding, and hogs following baby beeves.

Peanut meal and ground whole pressed peanuts for hogs, L. B. Burk (Texas Sta. Bul. 201 (1916), pp. 3-9).—The object of the experiments reported was to determine the value of both peanut meal and ground whole pressed peanuts when used as a supplement to milo maize chop in a ration for feeding hogs; to compare peanut meal and ground whole pressed peanuts with meat meal and cottonseed meal as supplements to milo maize chop; to compare a narrow peanut meal, milo maize ration with a similar balanced ration; to compare both rations with a ration of milo maize chop when fed alone; and to study the effects of peanut meal and ground whole pressed peanuts on the quality of the pork and lard.

Six lots, consisting of 10 each of pure-bred Duroc-Jersey hogs were fed the following rations for 77 days: Lot 1, milo maize chop alone; lot 2, milo maize chop 6 lbs., cottonseed meal 1 lb.; lot 3, milo maize chop 10 lbs., meat meal 1 lb.; lot 4, milo maize chop 7 lbs., peanut meal (without hull) 1 lb.; lot 5, milo maize chop 2.5 lbs., ground whole pressed peanuts 1 lb.; lot 6, milo maize chop 1 lb., peanut meal (without hull) 1 lb. The hogs were fed twice each day for two weeks, and after this they received all the feed they would clean up.

At the close of the experiment the animals were satisfactorily firm. Detailed results of the experiment and a financial statement are submitted in tabular form.

The average daily gains per head were 0.727, 1.26, 1.18, 1.21, 1.228, and 1.424 lbs., respectively. Lot 1, although producing a profit, was unsatisfactory when compared with the other lots, lot 2 returning 85, lot 3 70, lot 5 77, lot 4 81, and lot 6 105 per cent greater profits. The hogs of lot 2, although receiving an average of 0.75 lb. of cottonseed meal for the entire period of the experiment, showed no indications of cottonseed meal poisoning. Lot 6 produced the fastest and most economical gains of any of the lots. Although half of the ration fed to this lot was peanut meal, the pork was found to be firm.

After the animals were slaughtered various samples were taken from a medium sized and well-nourished hog of each lot, and the melting point and iodin number determined. The data are submitted in tabular form. A wide variation in the melting point was observed. With the exception of the back fat of lots 1 and 3 and the flank fat of lot 4, the melting points of all the samples of lots 1, 3, 4, 5, and 6 were found to be rather low and close together. The samples taken from lot 2 showed a much higher melting point. It is noted that this indicates "that cottonseed meal does have a hardening quality when fed in a balanced ration with milo maize chop." The samples of leaf fat in general showed a much higher melting point than the samples of fat taken from the back, shoulder, and flank.

Horse-breeding suggestions for farmers, H. H. Reese (U. S. Dept. Agr., Farmers' Bul. 803 (1917), pp. 21, flgs. 10).—A general discussion, under the topics of profit in breeding farm mares, selecting breeding and working mares, uniformity of the mares, soundness, selecting a stallion, mating considerations, feeding and management of mares in foal, abortions, approaching parturition, parturition, care of the foal, feeding after foaling, raising the orphan foal, and feeding and management of young horses.

Growing draft colts, C. W. McCampbell (Kansas Sta. Circ. 57 (1916), pp. 16, figs. 8).—A reprint of the article previously noted (E. S. R., 36, p. 172).

Chicken management on the farm, R. M. SHERWOOD, W. A. LIPPINCOTT, F. E. MUSSEHL, N. L. HARRIS, and F. E. MIXA (Kansas Sta. Circ. 60 (1917), pp. 23, flgs. 13).—This circular gives full general directions on the selection of stock, the farm breeding stock, selection and care of eggs for hatching, incubation, brooding, feeding, housing, and marketing poultry products.

Standard varieties of chickens.—I, The American class, R. R. SLOCUM (U. S. Dept. Agr., Farmers' Bul. 806 (1917), pp. 18, figs. 13).—A general description of the Plymouth Rock, Wyandotte, Java, Dominique, Rhode Island Red, and Buckeye breeds.

The capon, V. G. Auber (New Jersey Stas., Hints to Poultrymen, 5 (1917), No. 8, pp. 4).—A brief discussion of caponizing and the care and marketing of capons.

Fifth annual international egg-laying contest, W. F. KIRKPATRICK and L. E. CARD (Connecticut Storrs Sta. Bul. 89 (1917), pp. 255-301, flgs. 21).—A brief discussion is made of the growth of egg-laying competitions in the United States, and a detailed report is given of the fifth contest at the Storrs Station.

It is noted that the mash and grain mixtures used in the earlier contests (E. S. R., 36, p. 570) were made up of no less than 14 different feeds in various proportions, whereas the simplified formulas used in this contest necessitated the use of only eight ingredients, and these were, with two exceptions, mixed equal parts by weight.

The average annual egg yield per hen in the first four contests was 151.5 eggs. In the fifth contest, on the simpler rations, the hens averaged 162 eggs each for the year.

The scratch feed consisted of wheat and cracked corn (1:1). The dry mash was made up of wheat bran, corn meal, ground oats, flour middlings, fish scrap, and beef scrap (2:2:2:1:1).

The number of hens in the four principal breeds and their average pen scores at the opening of the contest were as follows: White Leghorns, 350 hens, score 91.8 per cent; Rhode Island Reds, 210, 87.2 per cent; Wyandottes, 170, 90 per cent; and Plymouth Rocks, 170, 88.1 per cent, respectively.

All the pens taken together laid 4,667 unrecorded eggs, or 2.88 per cent of the total egg yield.

Practically all of the 1,000 birds in the contest received the agglutination test for bacillary white diarrhea. Twenty-eight birds in 14 pens reacted positively to the test. In 4 of these 14 pens there were, respectively, 3, 4, 5, and 6 reactors. The average individual egg yield of these 4 infected pens was 130 eggs.

There was a loss by death during the contest of 10.4 per cent of the hens. About one-third of the deaths were due to various disorders of the reproductive system, and one-fourth to hypertrophied or enlarged livers.

In this contest the Plymouth Rock eggs averaged 26.4 oz. per dozen, the Rhode Island Red eggs 24.4 oz., the White Leghorn eggs 23.8 oz., the Wyandotte eggs 23.5 oz., and the remaining breeds 24.3 oz. The average weight of all eggs was 24.3 oz. per dozen. The number of eggs laid per month varied from 5,291 in November to 19,986 during May. The average value of all the eggs was 34.54 cts. per dozen, and the highest gross receipts for eggs was made in August.

The percentages of broody hens averaged from 13.6 for the White Leghorns to 65.6 for the Rhode Island Reds, the average for all the breeds being 39.3. The average number of days lost by each broody hen was 52.8. It is estimated that the combined loss in egg yield in this contest due to the 887 broody periods was 688.5 dozen eggs, worth \$237.81.

Tabulated data show the amount and cost of feed consumed, the number of eggs produced with their average weight and total value, and the returns above feed cost for each pen in the contest. The average amount of feed consumed for all breeds was 4.48 lbs. for each pound of eggs laid, or 6.81 lbs. for each dozen. The cost of feed (including grit, shell, and charcoal) per dozen eggs produced was 12.7 cts. for the Leghorns, 13.2 cts. for the Wyandottes, 15.1 cts. for the Rhode Island Reds, 15.5 cts. for the Plymouth Rocks, and an average of 14 cts. for all breeds. The cost data are based on a hundredweight valuation of \$1.93 for mash, \$2.11 for grain, \$0.75 for grit and oyster shells, and \$2 for charcoal. The cost of green food is estimated at 10 cts. per bird.

The text of the rules and regulations governing the contest, together with general information and suggestions, is included.

Breeding for egg production.—I, A study of annual and total production, E. D. Ball, B. Alder, and A. D. Egbert (*Utah Sto. Bul. 148* (1916), pp. 3-60, figs. 12).—Continuing previous work (E. S. R., 32, p. 73), this bulletin reports the results of a study of eight years' records of a flock of White Leghorn hens, with a similar study on the production of each successive flock of the unselected descendants.

From the data collected it is concluded that "the production of unselected White Leghorns varies widely in different years as influenced by the environment, but from all available records averages about 130 for the first year, 120 for the second, and less than 110 for the third, drops to about 85 in the fourth, and falls about 10 eggs a year after this up to the eighth year. Selected flocks have averaged 160 in America and 190 in Australia. The American record corresponds closely to the average of the upper one-half of the unselected flocks and indicates that the selection has been able to eliminate the lower half."

The first-year production of a flock of White Leghorns is considered to be no indication of their total production. If the first year's production is high, the second will be low, and vice versa. The total production in three years, however, will in all cases be about the same. "If the first year record of a flock is high, selection of the high layers will materially improve the later production of the flock. If the first record is low, there will be little value in selection, as even the lowest producer will make a second-year record above the general average. The three-year average is in all cases a much more reliable indication of productivity."

From the data at hand the average life of a White Leghorn appears to be about six years. The average production of the fourth year is equal to the average total production given for the United States. In general, the average total production is above 500 eggs and the maximum possible production above 1,000 eggs.

A list of 40 references to the cited literature is appended.

The separate inheritance of plumage pattern and pigmentation in Plymouth Rocks, R. Peabl. (Pract. Husb. Maine, 6 (1916), No. 2, pp. 567, 568; abs. in Maine Sta. Bul. 257 (1916), p. 354).—Experiments at the Maine Station are referred to, in continuation of those already noted (E. S. R., 23, p. 674), the results of which are said to indicate that pattern and pigmentation are distinct unit characters in Barred Plymouth Rock fowls. A brief report is also given of crossing experiments with White Plymouth Rock and Cornish Indian Game fowls, the results of which throw light on the probable nature of the mutation by which the White Plymouth Rock variety was produced, and indicate that White Rocks carry the factor for the barred pattern but lack the hereditary determiner for pigment.

On the effect of continued administration of certain poisons to the domestic fowl, with special reference to the progeny, R. Pearl (Proc. Amer. Phil. Soc., 55 (1916), pp. 243-258; Proc. Nat. Acad. Sci., 2 (1916), 7, pp. 380-384; abs. in Maine Sta. Bul. 257 (1916), pp. 352-354).—In the investigation here reported, which has a bearing on the general problem of the origin and causation of new, heritable variations, the method pursued was that of exposing systematically the germ cells of an animal to something unusual or abnormal in the surrounding conditions and then analyzing the results as shown in the offspring. The specific problems with which the investigation dealt are (1) whether the continued administration of certain narcotic poisons to the domestic fowl induces precise and specific changes in the germinal material such as to lead to new, heritable, somatic variations; (2) whether, if there is no specific effect, there is a general effect upon the germinal material; (3) the effects in general upon the soma of the treated individual of the continued administration of such poisons; and (4) whether the somatic effects upon the treated individuals are of a sort to give any clue to the probable origin or mechanism of the germinal changes.

The foundation stock used in these experiments came from pedigreed strains of two breeds of poultry—Black Hamburgs and Barred Plymouth Rocks. Both of the strains used had been so long pedigree-bred and used in such a variety of Mendelian experiments by the author that their genetic behavior under ordinary circumstances was fairly well known. Furthermore, the results of crossing these two breeds reciprocally have been thoroughly studied.

Three poisons were used in the work, namely, ether, methyl alcohol, and ethyl alcohol. These substances were administered to the birds daily by the inhalation method.

It is noted that "the egg production of the treated birds and the untreated controls was entirely normal in respect of its seasonal distribution, as well as in regard to its amount. There has been no significant difference in the egg production of the treated birds and their untreated control sisters, either in the total average number of eggs produced per bird nor in the seasonal distribution of this production. The only conclusion which can be drawn from the statistically insignificant differences which appear between treated and control birds is that the inhalation treatment has not affected the egg production of the birds either favorably or adversely.

"Regarding the offspring the results show that out of 12 different characters for which we have exact quantitative data the offspring of treated parents taken as a group are superior to the offspring of untreated parents in eight characters. The offspring of untreated parents are superior to those of the treated in respect of but two characters, and these are characters which are quite highly correlated with each other and really should be counted as but one single character. Finally with respect to two character groups there is no difference between the treated and the untreated."

The author interprets the results of the investigation as showing that "(1) there is no evidence that specific germinal changes have been induced by the treatment, at least in those germ cells which produced zygotes; and (2) there is no evidence that the germ cells which produced zygotes have in any respect been injured or deleteriously affected."

Studies on the physiology of reproduction in the domestic fowl.—XVI, Double eggs, Mayne R. Curtis (Biol. Bul. Mar. Biol. Lab. Woods Hole, 31 (1916), No. 3, pp. 181-212, pls. 3, figs. 7; abs. in Maine Sta. Bul. 257 (1916), pp. 348-351).—Double or inclosed eggs which were laid or found partly formed within the oviduct at autopsy are described and their formation discussed from a physiological standpoint. The specimens described are classified, according to their general structure, into double eggs with the inclosing egg a normal egg and the inclosed egg also normal or the inclosed egg a dwarf egg, and double eggs in which the inclosing egg does not contain a yolk but is simply a set of egg envelopes containing a normal egg or a dwarf egg.

In all the specimens examined the yolk was contained in the blunt end and the inclosed egg in the pointed end. Although one specimen has been described in which the yolk was found in the pointed and the inclosed egg in the blunt end of the inclosing egg, the accuracy of the observation is indicated as being doubtful.

The results of the study show that "a membrane-covered or hard-shelled normal or dwarf egg may be returned up the duct and may either meet its successor and return with it, becoming inclosed in a common set of egg envelopes, or not meeting its successor it may again be forced through the duct stimulating the secretion of a set of egg envelopes around itself.

"The number of egg envelopes common to the inclosed egg and the yolk of the inclosing egg or the number of egg envelopes which surround the inclosed egg when the inclosing egg has no yolk depends apparently on the level of the duct at which the inclosed egg resumes its normal direction toward the cloaca.

"The inclosed egg is usually forced up the duct without turning on its axis, but occasionally the poles are reversed. A similar reversal of poles sometimes occurs in normal laying, and it seems probable that in both cases this turning takes place in the uterus when the first powerful contractions of the uterus brings the outwardly directed end of the egg slightly above the opening from the shell gland into the vagina and tangentially against the curved caudo-dorsal angle of the uterus.

"The inclosed egg usually precedes its successor through the duct, and therefore usually lies in the pointed or anterior end of the inclosing egg, while the yolk of the inclosing egg lies in the blunt or posterior end. . . .

"A hard-shelled egg uncovered by membrane or albumin is sometimes found in the body cavity or upper oviduct, while a hard-shelled egg inclosed within another egg is not usually immediately surrounded by an egg membrane. It would, therefore, seem that the egg does not cause the secretion of egg envelopes around itself on its way up the duct. Since, in the case of a double-yolked egg, a second yolk closely following the first does stimulate the secretion of the successive envelopes, it does not seem probable that the failure of the duct to form envelopes around the returning egg is due to exhaustion of the glands. . . .

"The double egg results from a modification of the normal processes of egg formation due chiefly to a reversal in the direction of the egg after it has received its membrane or its membrane and shell. This backward movement must cease before the egg is expelled from the funnel mouth, and the movement in the normal direction must be resumed. If the backward movement sets in before the egg receives its membrane but stops before it is expelled from the funnel mouth and if the normal direction is then resumed, the result will be a normal egg with a large percentage of albumin or, in case the returned egg meets its successor, a double-yolked egg."

A double egg is deemed to be the result "of a combination of normal and abnormal processes which, when combined in other proportions, result in other abnormal phenomena of egg production."

## DAIRY FARMING-DAIRYING.

Report of the special milk board of the Massachusetts State Department of Health (Boston: State, 1916, pp. \$58, pl. 1, figs. 7).—This is the report of the special board of the State health department appointed in 1915 to investigate the status of milk production, distribution, and inspection, and the relation thereof to the health of the State. The report deals with the history and development of the present milk controversy in the State, together with summaries of proposed laws and present State laws relating to milk; statements from various persons and interests concerned in the milk question; data on the production, processing, and marketing of milk; the present official control of the milk supply of the State; the relation between cow's milk and public health; the grading of milk; and experiences of other localities. Appendixes give forms of and replies to various questionnaires and letters used in collecting data for the report, an abstract of milk-borne epidemics in the State during the past decade, effect of pasteurization on the chemical content of milk, status of local milk inspection, statistics of milk transportation into Boston, etc.

The feeding of dairy cows on pasture, R. A. Berry (West of Scot. Agr. Col. Bul. 76 (1916), pp. 15-48).—This is a detailed report of experiments conducted during 1912-1914 at several centers in the West of Scotland, the object of which was to ascertain the advantage or disadvantage of supplying extra feed to cows during the grazing season. In the experiments proper 224 cows were employed. In each test two lots, generally of 8 cows each, were pastured for three months from the middle of July. In addition one of the lots in each test was fed 2 lbs. per head daily for the first month and 4 lbs. during the second and third months of a mixture of decorticated cottonseed cake and soy bean cake.

Averaging the results secured during the three years it was found that the milk production of the lot fed concentrates was increased 1.9 per cent during the first month, 2.8 during the second month, and 4 per cent during the third month over that of the other lot. The average rise in the percentage of fat during the course of the experiment was more pronounced for the cows fed grass only than for those on concentrates. Apparently this was due to the action of the extra feeding in prolonging the lactation period. Valuing milk at 8d. per gallon the increase per cow due to feeding concentrates was 11s. 9d., and the cost of extra feed consumed per cow was £1 1s. 10d., making a deficit of 10s. per cow, of which 7s. 4d. is credited for the residual manurial value of the cakes.

A good bull's influence upon three generations, J. J. Dunne (Hoard's Dairyman, 53 (1917), No. 12, pp. 518, 519).—For the purpose of showing the value of cow-testing records, production records are given of the offspring of a number of bulls in one family in Denmark, indicating in general that the influence of these sires was good.

The fat content of the milk of the offspring was almost always increased, and in many cases the amount of milk was increased, as compared with their dams. It is stated that "when the average milk yield and fat percentage of a herd are lower than those inherited by the bull from his dam and granddams, the offspring resulting therefrom will be found to have, in the majority of cases, more milk and a higher fat percentage than their dams. On the other hand, when the milk and fat records of a herd average higher than those inherited by the bull, the opposite is generally the case."

The yield and composition of cows' milk during lactation, R. A. Berry (West of Scot. Agr. Col. Bul. 76 (1916), pp. 49-73, figs. 6).—The author gives results of a preliminary study of the effects of individuality on the changes in the yield and composition of milk during lactation as shown in the case of three cows.

The effect of advance in lactation on milk yield followed much the same order of variation in the case of two of the cows, but differed greatly in the third. Data from the milk records of a large number of cows show that the milk yield generally rises for the first two months after calving, after which it falls more or less regularly until the end of the lactation period. These milk records also show that the fat content of the milk generally falls in the second month after calving, followed by a gradual rise thereafter. With one of the three cows under observation the fat content of the milk showed little variation throughout the lactation period. Apart from the normal effects due to advance in lactation, the fat content of the milk of the other two cows was appreciably influenced by change of environment and feed. Other changes in the milk and milk fat of the three cows due to advance in lactation are discussed.

Notes on modern dairy chemistry, W. VAN DAM (Opstellen over Moderne Zuivelchemie. The Hague: Alg. Nederland. Zuivelbond, 1916, pp. 180, figs. 12).—This volume discusses the true acidity of milk and its effect on curdling; the antiseptic action of the acidityof whey used for feeding; the influence of the hydrogen ion concentration on the growth and destruction of colon and typhoid bacilli; the action of microbial lipase in relation to the true acidity of dairy products; erroneous ideas in regard to the acidity of cheese mass; acidity of the curds of Edam and Emmental cheese and its significance; relation of acidity to cheese ripening; the influence of temperature on the physical condition of the milk fat; the preparation of Edam cheese, using pepsin in place of rennin; and closely related topics.

Cream production and grading in Kansas, G. S. Hine (Kansas Sta. Circ. 56 (1916), pp. 4, fig. 1).—Brief essentials are outlined.

The changes in the composition of Cheddar cheese during the process of ripening, R. A. Berry (West of Scot. Agr. Col. Bul. 76 (1916), pp. 74-78).—The Cheddar cheese used in this preliminary experiment was made from milk in which a pure culture of Streptococcus lacticus was used as a starter.

Due to a continuous loss of water the total nitrogen showed a gradual increase from the beginning to the end of the ripening period. The water-soluble compounds rose from about 3 per cent of the total nitrogen in the green cheese to 37 per cent by the ninth month, when the experiment ended. There was also a small but persistent rise in the amount of the ammonium compounds. No

trace of sugar was found after the second or third month of ripening. The acidity, expressed in terms of lactic acid, rose from 0.94 per cent in the green cheese to 2.05 per cent in the fifth month, after which it gradually decreased to 1.75 per cent in the ninth month. The moisture decreased from 35.6 per cent in the green cheese to 32.1 per cent at the end of the test. During the nine months' curing there was a loss in weight of about 7 per cent.

Paying for milk in cheese making, H. C. Thoy (Hoard's Dairyman, 53 (1917), No. 15, pp. 647, 648).—The author gives data indicating that when the increased energy value of cheeses made from milk of higher fat content is taken into consideration, payment for milk on the fat percentage basis is equitable.

## VETERINARY MEDICINE.

Second biennial report of the Oregon State Live Stock Sanitary Board for the year ended November 30, 1916, W. H. Lytle et al. (Bien. Rpt. Oreg. Live Stock Sanit. Bd., 2 (1915-16), pp. 127, figs. 18).—The three parts of this report deal, respectively, with finances and legislation, the occurrence of and work with infectious diseases of live stock, etc., particularly tuberculosis, contagious abortion, and hog cholera, and a report of the Board of Sheep Commissioners, dealing especially with the occurrence of sheep diseases.

Report of the parasitologist, J. W. Scott (Wyoming Sta. Rpt. 1916, pp. 88-91).—In reporting upon the transmission of swamp fever in horses, in continuation of work previously noted (E. S. R., 32, p. 754), it is stated that circumstantial evidence points very strongly to the stable fly as one of the agents implicated in its transmission, and that transmission experiments with mosquitoes have given negative results.

Feeding experiments with Tania (Moniezia) expansa have failed to produce infestation in lambs. Further work with Thysanosoma actinioides has helped to substantiate the conclusion that standing water, or at least a swampy area, is a necessary condition for infestation. The work with Sarcocystis tenella shows that lambs may become infested with this sarcocystid by eating grass and certain kinds of insects.

[Report of the] division of animal industry, V. A. Nörgaard ([Bien.] Rpt. Bd. Comrs. Agr. and Forestry Hawaii, 1915-16, pp. 119-165, pls. 12).—In the main part of this report the author and L. N. Case report upon the occurrence of and work with diseases of live stock, particularly hog cholera and bovine tuberculosis. The report of the live-stock inspector, J. Richard (pp. 138-143), and the reports of four deputy territorial veterinarians are appended.

Animal diseases in Russian Turkestan caused by endoglobular parasites, W. L. Yakimoff et al. (Bul. Soc. Path. Exot., 10 (1917), No. 4, pp. 302-311).— This article deals with the piroplasmoses, theilerioses, nuttallioses, and anaplasmoses.

On the development of Ascaris lumbricoides and A. suilla in the rat and mouse, F. H. Stewart (Parasitology, 9 (1917), No. 2, pp. 213-227, pl. 1, figs. 9).—It has been found that when eggs of A. lumbricoides or A. suilla containing mature embryos gain entrance to the alimentary canal of the sewer rat (Mus decumanus) or the mouse (M. musculus) they hatch. A certain proportion of the larvæ thus liberated escape in the feces where under suitable circumstances they live for at least three days, but probably ultimately succumb. The majority of the larvæ gain entrance into the body of the host, some animals showing signs of illness as soon as the second day after infection.

"Larvæ are found in the lungs and liver of the host not later than four days after infection and possibly as early as two days. . . . Larvæ are not found

in the liver after the fifth day from infection. They are found in the bronchi about the seventh day and in the trachea on the eighth day. No larvæ are found in any portion of the lung on the ninth day after infection. Dead larvæ have been found in the stomach and rectum on the ninth day after the last infection." The route by which the larvæ reach the lungs, liver, etc., is either by boring through the wall of the stomach or intestine and entering a mesenteric venule or by traveling up the bile duct.

Spirochæta morsus muris n. sp., the cause of rat-bite fever, II, K. Futaki, I. Takaki, T. Taniguchi, and S. Osumi (Jour. Expt. Med., 25 (1917), No. 1, pp. 33-44, pls. 3, fig. 1).—In this second paper (E. S. R., 35, p. 783), the authors record five additional cases in each of which a spirochete has been found. In two of the patients examined the spirochete was taken in the circulating blood derived from a vein or the punctured skin.

"The organism is not present in the blood of all rats, and there is no relation between the species of the rat and the ratio of infection. We have never found the spirochete in healthy guinea pigs or mice. By permitting a rat infected with the spirochete to bite a guinea pig, the latter develops the disease. We have succeeded in cultivating the spirochete in Shimamine's medium.

"Among the spirochetes described in the literature or discovered in the blood of rats and mice there may be some resembling our spirochete, but none of the descriptions agree with it fully. Hence, we have named our organism *Spirochata morsus muris* and regard it as belonging to the Spironemacea of the nature of treponema. . . .

"The spirochete can be detected in about 3 per cent of house rats. These facts enable us to identify the cause of the disease."

**Experimental rat-bite fever**, K. Ishiwara, T. Ohtawara, and K. Tamura (*Jour. Expt. Med.*, 25 (1917), No. 1, pp. 45-64, pls. 2, figs. 6).—Spirochetes have always appeared in the peripheral blood when a mouse or white rat was inoculated, although no other symptoms developed.

"Spirochetes disappear from the blood of the animals as a result of the injection of salvarsan, thus indicating that the spirochete is arsenotropic."

Toxic action of copper compounds of amino acids on protozoa, J. A. Shaw-Mackenzie (*Jour. Physiol., 51 (1917*), *No. 1-2, pp. III, IV*).—Investigations show the copper compounds of organic acids to possess a high toxicity for protozoa.

The action of digitalis in pneumonia, A. E. Cohn and R. A. Jamieson (Jour. Expt. Med., 25 (1917), No. 1, pp. 65-81, pl. 1).—" Digitalis acts during the febrile period of pneumonia. It produces a beneficial, possibly a life-saving effect in cases of auricular irregularity (fibrillation and flutter). Whatever beneficial action it has on the function of the normally beating nonfebrile heart may be expected from its use in the febrile heart in pneumonia."

A bibliography of 23 titles is appended.

Studies on the blood proteins.—II, The albumin-globulin ratio in experimental intoxications and infections, S. H. Hurwitz and G. H. Whieple (Jour. Expt. Med., 25 (1917). No. 2, pp. 231–253, figs. 3).—Continuing the work previously noted (E. S. R., 36, p. 778), the authors have found that "the intoxication which develops as the result of a simple obstruction or a closed intestinal loop is accompanied by definite changes in the coagulable proteins of the blood serum. These changes consist essentially in an alteration in the normal albumin-globulin ratio; the globulin fraction is greatly increased and at times the normal relation of the two fractions may show a complete inversion."

The infections and intoxications produced by inflammatory irritants were accompanied by a rise in the blood globulins. It is indicated that this sug-

gests that tissue disintegration with absorption of toxic products is responsible for the changes noted, and that bacterial invasion is important only in so far as it gives rise to toxic substances. The most marked increase in globulin content of the blood serum was found in animals which showed some of the complications met with in loop animals, as rupture of the loop and peritonitis. The globulin increase was especially rapid and large in the latter condition. This reaction is deemed to be of diagnostic value in acute infections.

The expermental data are submitted in tabular and graphical form and discussed.

The mechanism of the agglutination reaction, H. PRIESTLEY (Jour. Hyg. [Cambridge], 15 (1917), No. 4, pp. 485-504).—From the study reported the author concludes that the agglutination and precipitin reactions are probably essentially the same in nature. "The agglutination of bacteria by specific sera is probably due to the formation of altered serum protein in and around the bacteria and the subsequent flocculation by electrolytes of this altered protein and the bacteria. This altered protein is probably altered serum globulin, and possibly other altered serum proteins."

The inhibition phenomenon exhibited on heating an agglutinating serum was found to resemble closely the inhibition by acids and alkalis. The inactivation of an agglutinating serum by heating and the production of "zones of inactivation" are deemed probably due to the formation of inhibitory substances rather than to the destruction of the agglutinin.

The data are reported in detail and discussed.

On factors limiting the extent of the concentration of antitoxic sera by the fractional precipitation methods at present employed, Annie Homes (Jour. Hyg. [Cambridge], 15 (1917), No. 4, pp. 580-590).—Detailed tabular experimental data submitted show that a product containing not more than 20 per cent of protein and having a potency eight or ten times that of the original serum can be obtained where the pooled antidiphtheritic sera have a unitage not greater than 500 and where the heat denaturation is about 40 per cent.

It is noted that with the methods at present employed for the concentration of an antitoxic serum for therapeutic use, a concentration of more than 22,500 units of antitoxin per gram of protein can not be obtained.

See also previous notes (E. S. R., 35, p. 680; 36, p. 178).

The effects of serum treated with pararabin, E. Zunz and C. Mohilevith (Jour. Expt. Med., 25 (1917), No. 2, pp. 211-229).—Horse serum treated with pararabin (a portion of the carbohydrate of agar practically free from nitrogen), as previously noted by Zunz and Gelat (E. S. R., 36, p. 575), produced the same results as when treated with agar.

A preliminary report on two new methods of preventing blackleg by means of an antiblackleg serum and an aggressin, F. S. Schoenleber, T. P. Haslam, and O. M. Franklin (Kansas Sta. Circ. 59 (1917), pp. 7).—The authors describe the preparation of a highly potent antiblackleg serum from the horse. The serum was found to be curative for calves in the early stages of the disease. The passive immunity produced, however, is of short duration, and in order to produce an active immunity of a certain degree virus pellets are administered a few days after the serum treatment.

The edematous fluid sterilized by filtration through a Berkefeld N filter in doses of from 8 to 15 cc. possessed a strong immunizing power and was found sufficient to protect calves against doses lethal for nonvaccinated animals,

The vaccine has been found to yield excellent results in field treatment in doses of 5 cc., producing in calves six months of age or older sufficient immunity to protect them for the remainder of their susceptible period.

Some considerations on the new dual theory of Carrion's disease, J. Arce (Crón. Méd. [Peru], 33 (1916), No. 641, p. 377; abs. in Jour. Amer. Med. Assoc., 68 (1917), No. 4, p. 318).—The author's long years of experience in Peru have confirmed more and more the view that Peruvian verruga and Oroya fever are the benign and the malignant forms of one and the same disease. He has failed to find any proof of the zooparasitic nature of the inclusions in the red corpuscles referred to in the report by Strong et al. noted on page 356 as Bartonella bacilliformis.

Gaseous gangrene.—Bacillus ædematous and antiedematous serum, M. Weinberg and P. Séguin (Compt. Rend. Acad. Sci. [Paris], 164 (1917), No. 9, pp. 365-368).—The organism B. ædematous, isolated from a number of cases of gaseous gangrene, was found to be highly pathogenic. A highly antitoxic and prophylactic serum was prepared by the injection of the organism into a horse. This antiserum was found to yield excellent results in the treatment of gaseous gangrene caused by B. ædematous in removing the focus of the gangrene.

The reversible precipitation in glanderous serum, M. Belin (Compt. Rend. Soc. Biol. [Paris], 79 (1916), No. 20, pp. 1095-1098).—The author notes the formation of a precipitate on heating the serum from a glanderous horse. The precipitate appears at 47° C. and increases in amount rapidly until the temperature reaches about 55°, at which point the serum is very turbid. Further heating to about 60 to 61° dissolves the precipitate completely if the heating be rapid enough. If this solution temperature is attained rapidly enough and the material then placed in cold water a reprecipitation takes place. It is indicated that the substance precipitated is not a globulin but an albumin.

The serum in contact with the clot or preserved alone in a test tube forms a precipitate as well as the serum preserved with an antiseptic.

The reaction was not found to be uniform. A general parallelism was, however, noted between the intensity of mallein reactions and the amount of precipitation. The positive reversible precipitation reaction is considered to indicate an unpromising prognosis in glanders. The injection of mallein was found not to influence the reaction in any way.

The culture of the causative organism of epizootic lymphangitis, A. Boquet and L. Négre (Bul. Soc. Path. Exot., 10 (1917), No. 4, pp. 274-276).—The authors' studies indicate that the causative organism of epizootic lymphangitis belongs to the genus Endomyces.

Treatment of epizootic lymphangitis by potassium iodid, J. Cartier (Rec. Méd. Vét., 92 (1916), No. 21, pp. 614-618; abs. in Vet. Rev., 1 (1917), No. 2, pp. 131, 132).—In the treatment of epizootic lymphangitis the author has found potassium iodid to give satisfactory results when administered in doses of from 12 to 20 gm. daily. It was found desirable to divide the daily dose and also to interrupt the course of treatment by periods of from seven to ten days during which the drug is not given. Seven cases are reported upon.

Pseudotuberculosis in guinea pigs, R. Van Saceghem (Compt. Rend. Soc. Biol. [Paris], 79 (1917), No. 17, pp. 908, 909).—The author notes an outbreak of pseudotuberculosis in guinea pigs which were used in a study on the treatment of trypanosomiasis in animals. The symptoms of the disease, together with the post-mortem findings, are described.

An organism which could not be distinguished morphologically from the plague bacillus was isolated from the tubercles which were found at autopsy. On being injected into normal animals the organism reproduced the disease. A vaccine made by heating a bouillon culture of the organism at 60° C. for two hours and injected subcutaneously in doses of 1 cc. protected the animals against a subsequent subcutaneous injection of the virulent organism.

The possibility of preparing a vaccine against human plague from the organism isolated is indicated.

Pseudotuberculosis in a South American horse, Bringard (Rec. Méd. Vét., 93 (1917), No. 1-2, pp. 33, 34).—The symptoms, treatment, and post-mortem findings of a case observed at a military depot are reported.

Tuberculosis, R. A. CRAIG and C. H. CLINK (Indiana Sta. Circ. 60 (1917), pp. 8, figs. 7).—This circular discusses the subject under the topics of occurrence, symptoms, effect on the different body organs, tuberculin testing used in detecting tuberculosis, and controlling tuberculosis in cattle and hogs.

The infection of tuberculosis through air expired during coughing, P. Chaussé (Ann. Inst. Pasteur, 30 (1916), No. 11, pp. 613-641, figs. 2).—Experimental data are submitted and discussed in detail, together with a description of the procedure and apparatus used in the study.

It is concluded in general that the possibility of infection through air expired during coughing is definitely established by the results obtained. The infection depends on the direct inhalation of the fine droplets formed during coughing from the saliva and sputum. The extreme infectivity of tuberculosis is indicated and the great need for a rational prophylactic campaign emphasized.

Contribution to the study of delayed or "latent" tuberculous infection, S. Delépine (Ann. Inst. Pasteur, 30 (1916), No. 11, pp. 600-612).—Inoculation experiments with guinea pigs, using artificially and naturally infected tuberculous milk, are reported and discussed.

Untreated (control) and treated milk (to various temperatures) was used for the injections. The animals which received the untreated milk developed extensive tuberculous lesions at the seat of inoculation in two weeks, while animals treated with a much larger dose of the same tuberculous product, previously heated, developed only slight lesions at the seat of inoculation in the course of 11 weeks. The postmortem findings were similar to the lesions developed at the seat of inoculation.

Tubercle bacilli were found still living and capable of a modified pathogenic action after being kept for nearly 500 days in milk. It is indicated that this "supports the view that under certain circumstances tubercle bacilli are still infective after remaining dormant for a considerable period of time."

Post-mortem and other experimental data are submitted in tabular form.

Types of tubercle bacilli in cervical and axillary gland tuberculosis, A. S. Griffith (Lancet [London], 1917, I, No. 6, pp. 216-218).—Continuing previous work, the author reports the bacteriological examination of material from 52 persons suffering from enlarged cervical or axillary lymphatic glands. The material examined consisted of glands removed by surgical operations and pus aspirated from the abscesses or collected from the dressings of the lesions.

The material from 35 cases produced tuberculosis in guinea pigs, and cultures of the tubercle bacilli were isolated either directly from the original material or through the test animals. Fifteen of the 35 strains were of standard bovine type, 17 of the human type, and 3 atypical. Two of the atypical cultures were obtained from cervical glands, while the third was derived from an intramuscular abscess in a patient also suffering from tuberculosis of the cervical glands.

The experimental results of the three atypical cases are reported in detail, together with a general tabulated summary of statistical data of previous work and that here reported. See also a previous note (E. S. R., 35, p. 576).

Bovine tuberculosis in the horse, E. Fröhner (Monatsh. Prakt. Tierheilk., 26 (1914), No. 1-2, pp. 5-10).—The clinical data and post-mortem findings of a case are reported in detail.

Observations bearing on the possibility of developing an experimental chemotherapy of tuberculosis, P. A. Lewis (Bul. Johns Hopkins Hosp., 28 (1917), No. 313, pp. 120-125).—This is a general discussion of the subject, together with experimental data on the disinfectant action of phenol, resorcin, and several organic dyes on the tubercle bacillus. The tubercle bacillus was found to be considerably more susceptible to the action of disinfectants than is ordinarily considered.

Eradicating bovine tuberculosis, W. H. PEW (Breeder's Gaz., 71 (1917), No. 19, pp. 968, 970).—The author reports upon the successful eradication of tuberculosis from the Iowa Agricultural College herd by means of the "modified Bang system," suggested by E. C. Schroeder of the U. S. Department of Agriculture as a possible method for managing a reacting herd with the least cost and minimum loss.

The cows were maintained absolutely in quarantine, kept in the open winter and summer, and fed in the open. The calves were dropped in the quarantine pasture and permitted to remain with their dams until weaning time, which was from 6 to 11 months of age. They were then tested, retested in from 60 to 90 days, and then taken to the clean herd. Of 21 calves tested that were dropped in quarantine from 1908 to 1914 and permitted to nurse their dams until weaning time 18 passed the test and 3 reacted. At the time the quarantine herd was discontinued in 1915, only two animals were left, the others having died or were sold.

The results tend to show that it is not necessary to discard reacting animals and that calves can be kept with cows in open conditions with a fair degree of safety. Whenever it is found that a cow under this system produces two calves in succession that are reactors at weaning time, it may be suspected that this cow is a contaminating factor through the udder, which is probably affected.

Sterility of cattle and methods of treatment, J. Albrechtsen (Cornell Vet., 7 (1917), No. 2, pp. 57-110).—This account, a translation from the Danish, deals with the subject at length under the headings of treatment of sterility, diseases of the uterus, diseases of the ovaries, cystic degeneration of the evaries, diseases of the vagina, and results.

Prevention and treatment of hemorrhagic septicemia of cattle by the use of bacterial vaccine made from the causative agent, T. O. Brandenburg (Jour. Amer. Vet. Med. Assoc., 51 (1917), No. 1, p. 93).—The use of a vaccine in a number of cases is noted. From the results the author considers the vaccine to be "an absolute preventive if properly used and curative in all cases which are not advanced."

Two injections about eight days apart are considered necessary to establish a positive protection. Younger animals were found to be more susceptible to the disease and also to treatment than older animals.

Diseases of new-born calves and outline of recommendations for control, W. L. WILLIAMS (Cornell Vet., 7 (1917), No. 2, pp. 110-134).—This article, prepared by the author in cooperation with the Bureau of Animal Industry of the U. S. Department of Agriculture, is part of an extensive report upon investigations of contagious abortion of cattle to be published in the annual report of the New York State Veterinary College.

Anaphylaxis in cattle and sheep, produced by the larvæ of Hypoderma bovis, H. lineatum, and Œstrus ovis, S. Hadwen and E. A. Bruce (Jour. Amer. Vet. Med. Assoc., 51 (1917), No. 1, pp. 15-44, figs. 15).—Experiments are reported in which anaphylaxis was produced in cattle, sheep, rabbits, and guinea pigs with extracts of the larvæ of H. lineatum, H. bovis, and O. ovis.

The reactions could be induced by crushing and returning an extract of an animal's own larvæ into the jugular vein, showing that larvæ living in the animals make them receptive.

Natural cases of anaphylaxis were observed where injury had ruptured the larvæ subcutaneously, liberating the contents in sufficient quantity to produce shock. Immunity lasting for varying periods was observed in animals which recovered from the reaction. Eye and other local reactions were obtained with extracts of the larvæ applied to the mucous membranes. The reaction was specific in cattle for extracts of Hypoderma, and in a horse for Gastrophilus.

The symptoms produced were those previously noted (E. S. R., 36, p. 478), which work is also included in this paper.

The etiology of bradsot or braxy, C. O. Jensen (Ztschr. Infektionskrank. u. Hyg. Haustiere, 17 (1915), No. 1-2, pp. 1-18, pls. 4; abs. in Jour. Compar. Path. and Ther., 29 (1916), No. 2, pp. 179-181).—After reviewing recent literature relating to the etiology of bradsot, the author reports upon the results of investigations, including the details of ten cases, conducted with a view to demonstrating that the so-called bacillus of braxy is more than an agonal invader.

In all cases the typical lesions of braxy were present in the fourth stomach, and the braxy bacillus was demonstrated in pure culture in the altered parts of the mucous membrane and in the infiltrated submucous tissue. Since the pathological changes in the abomasum are characteristic of a primary infection which closely resembles malignant edema, and the bacilli which occur in the wall of the abomasum and later in the blood when inoculated into sheep produce characteristic lesions which closely resemble those observed in malignant edema, there can be no reasonable doubt as to the causal connection of the bacillus with bradsot.

On a tick-borne gastroenteritis of sheep and goats occurring in British East Africa, E. Montgomery (Jour. Compar. Path. and Ther., 30 (1917), No. 1, pp. 28-57, flgs. 6).—Hemorrhagic gastroenteritis of sheep and goats appears to be epizootic in British East Africa, principally in the Kikuyu region. Grade and pure-bred sheep are more resistant than native sheep, in which the mortality is about 70 per cent of those attacked.

The disease is carried by the brown tick (*Rhipicephalus appendiculatus*) and possibly by other ticks. Ticks which as nymphs have fed upon affected sheep convey the infection after arriving at the adult stage. It is possible that the larvæ from adults which have fed on sick animals may also transmit the disease.

No success has yet been obtained from different methods of preventive inoculation, the most favorable measure appearing to be that of attenuating the virulence of the disease for sheep by passing the virus for several generations through the more resistant goat. The eradication of ticks capable of carrying the disease forms the basis of preventive measures.

Morphology of normal pigs' blood, C. C. Palmer (U. S. Dept. Agr., Jour. Agr. Research, 9 (1917), No. 5, pp. 131-140).—The author at the Minnesota Experiment Station reports the examination of the blood of 25 normal pigs between the ages of 2 and 42 days. The average number of erythrocytes was 3,855,000 per cubic millimeter, and 13,500 leucocytes per cubic millimeter. The average clotting time was 64 seconds, specific gravity 1.024, and hemoglobin percentage 56.8. The differential count of the leucocytes yielded the following percentages: Lymphocytes, 63.25; polymorphs, 32.14; mononuclears, 2.63; eosinophils, 1.28; and mast cells, 0.24.

Twenty-five examinations of the blood of pigs weighing in the neighborhood of 100 lbs. showed the average number of erythrocytes per cubic millimeter to be 6,215,000, and the average number of leucocytes, 18,000. The average clotting time was found to be 57.6 seconds, specific gravity 1.062, and hemoglobin percentage 79.4. The differential leucocyte count yielded lymphocytes 55.21, polymorphs 39.79, mononuclears 0.79, eosinophils 3.42, and mast cells 0.79 per cent.

A detailed description of the various classes of leucocytes observed in the investigation is submitted. The average differential counts in male and female animals were found to be about the same, and also the counts by various workers to be fairly uniform. The number of erythrocytes was found to vary under different conditions, and to be higher in an animal in good condition than in an animal of the same age in poor condition.

Effects of muscular exercise and the heat of the sun on the blood and body temperature of normal pigs, C. C. Palmer (U. S. Dept. Agr., Jour. Agr. Research, 9 (1917), No. 6, pp. 167-182, figs. 2).—This report of investigations at the Minnesota Experiment Station has been summarized by the author as follows:

"Blood examinations in normal resting pigs, covering a period of 24 hours, may be quite uniform; but in some animals there is marked variation throughout the period. . . . Results based on only one or a few experiments may lead to wrong conclusions, owing to the variability in the blood of pigs."

"Observations made upon a number of animals lead to the conclusion that muscular exercise does not cause an increase of red corpuscles in the peripheral circulation of the pig. . . . Evidence given by work with the pig tends to confirm the theory of perspiration being responsible for the increase in the number of red corpuscles following muscular exercise in man.

"Muscular exercise in the pig is usually followed by a leucocytosis. This leucocytosis is probably the result of muscular exercise forcing leucocytes into the general circulation from the tissues. Muscular exercise leads to marked changes in the differential counts. The mononuclear elements are decreased, and the polymorphonuclear elements are increased. The height of the curve is reached several hours after exercise, and the normal proportions do not return for many hours.

"Exposure to the sun causes similar changes in the differential curve. These changes under both conditions are the result of increased rate of aging of the leucocytes, the cells becoming older faster than young cells are being produced. Muscular exercise and heat of the sun lead to a marked increase in body temperature. Body temperature changes are more pronounced in fat pigs than lean ones, but even in pigs weighing from 75 to 100 lbs. marked changes are likely to occur.

"Increased atmospheric temperature and increased percentage of humidity lead to increased body temperature.

"Blood examinations of pigs which are to be used for clinical records should be taken from animals which have been confined in a small cool pen for at least 24 hours, and better, 48 hours. The animals must be kept absolutely quiet and not worried. Feeding and watering should be regular. The daily blood examinations should be made at the same time on each day.

"Temperature records which are to be used for clinical records should be taken from pigs kept in a cool, shady pen. The animals should not be exercised or worried when the temperatures are taken. If the animals are chased around the pen in endeavoring to obtain the temperature, the last temperatures taken may show a marked rise. For tuberculin work where the temperatures are used it would be best to keep them confined in a crate throughout the test.

"The condition of the animal (amount of fat), the temperature of the atmosphere, and the percentage of humidity are factors which should be considered in determining the normal temperature of the pig."

The etiology of hog cholera.—Preliminary report, F. Proeschek and H. A. Seil (Jour. Amer. Vet. Med. Assoc., 51 (1917), No. 1, pp. 64-69, pls. 2).—The authors prepared smears from the blood of 6 pigs in the advanced stages of hog cholera and from the blood of 28 pigs artificially infected with virus. All the animals were examined post-mortem and the characteristic lesions of the disease established.

The smears, after being fixed, were thoroughly washed and then stained in a 1 per cent aqueous solution of methylene azure containing 1 per cent of phenol and finally mounted in paraffin or cedar oils. The general blood pictures are described in detail.

In all the preparations a very small diplococcus uniformly less than 0.2  $\mu$  in size was found. They were stained either a deep blue or a metachromatic violet. The micro-organisms were also found in the urine of three pigs artificially infected with hog-cholera virus.

The close resemblance of the changes in the blood picture in hog cholera to those of typhus fever is pointed out and briefly discussed.

The artificial cultivation of the organism observed in the smears and a histological study of the changes taking place in the blood vessels of animals affected with cholera are in progress.

On the pathology and treatment of pernicious and infectious anemia of the horse, III, J. N. Ries (Rec. Méd. Vét., 92 (1916), No. 1-2, pp. 14-20).—It is concluded that the pernicious anemia of Lorraine and adjacent territory is a gastrophilic anemia in the great majority of cases.

Vaccination against infectious arthritis of foals due to Bacillus abortus equi, J. B. Hardenbergh (Mo. Bul. State Live Stock Sanit. Bd. [Penn.], 1 (1916), No. 2, pp. 16, pls. 3; Jour. Amer. Vet. Med. Assoc., 50 (1916), No. 3, pp. 331-349, figs. 6).—A number of cases in an outbreak of infectious arthritis in foals are reported in detail. The organism causing the outbreak was found to belong to a subgroup of the paratyphoid-enteritidis group which has been isolated by various investigators.

The complement-fixation and agglutination tests are deemed reliable for determining the extent of the infection in the stable, but the best results are obtained by repeating the tests at intervals of from three to four weeks. "Animals giving an agglutination reaction of 1:500 or over, with no complement-fixation reaction, should be watched and retested in three weeks. Immune bodies in some cases disappear rapidly."

One ophthalmic test with a purified "abortin" is considered to be of no value in determining infected animals. The possibility of using a different preparation of abortin or a retest as yielding more satisfactory results is indicated. Two or three injections of from 50,000,000 to 100,000,000 organisms, followed by more if necessary, are considered to be much better than numerous injections of small amounts.

"The fact that all of the colts, either infected or later developing affections of the joints, gave marked local reactions to the bacterin may indicate such a preparation to be of diagnostic value when injected or rather vaccinating foals against joint evil, which do not at the time give serum reactions. Vaccination of exposed foals with a specific bacterin appears to confer some immunity to the disease, and may also have some curative properties, as 7 out of 10 foals, either thoroughly exposed to the infection or badly infected, failed to develop

or completely recovered from a severe attack of infectious arthritis. Owing to the fact that we were unable to try the vaccine on a large number of animals experimentally, we hesitate to base our conclusions too strongly on results obtained, and they should be confirmed."

Tabulated data of complement-fixation tests and complement-fixation, agglutination, and ophthalmic reactions, together with some other data, are submitted.

Bacillary white diarrhea of young chicks.—VI, Second progress report on the elimination of infected breeding stock, L. F. RETTGER, W. F. KIRKPATRICK, and R. E. Jones (Connecticut Storrs Sta. Bul. 88 (1916), pp. 247-254).—A brief summary is first given of the more significant data obtained in a systematic campaign against bacillary white diarrhea in Connecticut, inaugurated in June, 1914, a detailed report on the methods and results of which for the first year has been previously noted (E. S. R., 35, p. 184).

During the second year (1915–16), in which the agglutination test was applied to 7,799 fowls in 78 flocks, of which 25 flocks failed to react and were regarded as free from ovarian infection, the average percentage of infection was 8.2 as compared with 10.24 for the previous year. As before, ovarian infection was again less prevalent in the White Leghorn than in the heavier breeds, only 3.4 per cent of 2,870 Leghorns examined being infected while the average for 3,178 Plymouth Rocks, Wyandottes, and Rhode Island Reds was 11.45, and for a single lot of Orpingtons 31.7 per cent.

While the elimination of reacting hens from breeding stock has a far-reaching influence on the health and condition of the future chicks the work has shown that a single set of agglutination tests and the elimination of reactors is not an absolute guaranty that the flock is entirely rid of ovarian infection. Single tests have, however, on numerous occasions sufficed to stamp out completely the infection from the breeding stock and the results thus far obtained are said to have been very gratifying. Many tested and nonreacting flocks of almost all breeds have been located in the State, so that buyers of eggs for hatching and day-old chicks should have no trouble in procuring stock which has a thoroughly clean known record.

A simplification of the technique employed in testing has made possible the reduction of the cost of the agglutination test in all but small flocks. Instead of making two transfers of the blood serum as was formerly done, 0.03 cc. of the serum in the original blood tube is introduced directly into 3 cc. of the test blood in which the final observations are made.

A summary of the work of the first two years of the campaign shows that 9.3 per cent of 21,317 hens and 2.1 per cent of 1,037 males tested were found infected.

Enterohepatitis or blackhead in turkeys, C. H. HIGGINS (Jour. Amer. Assoc. Instr. and Invest. Poultry Husb., 3 (1917), No. 8, pp. 57, 58).—The data here presented have been substantially noted from another source (E. S. R., 36, p. 384).

Some field experiments bearing on the transmission of blackhead in turkeys, T. SMITH (Jour. Expt. Med., 25 (1917), No. 3, pp. 405-414).—The author's experiments show that healthy turkeys may be raised from the eggs of infected flocks when all older turkeys and poultry are kept away and the ground has not been used before, there being no evidence favoring the theory that the protozoan parasite can be transmitted in the egg. In these experiments all the turkeys remained well until August 14, the end of the hen exposure test, when they were 12 weeks and 4 days old. The first death occurred 2 weeks after the beginning of exposure to actual disease, when they were more than

14 weeks old. Hens from a blackhead farm and from a farm free from turkeys did not convey the disease to the incubator turkeys on uninfected land.

It is concluded that the infection is either not transmitted at all or only under exceptional conditions by turkeys in the early acute stage. It is considered as probably carried and shed by those birds which have successfully passed through an attack.

Note on coccidia in sparrows and their assumed relation to blackhead in turkeys, T. Smith and E. W. Smillie (Jour. Expt. Med., 25 (1917), No. 3, pp. 415-420).—This is a report of an investigation carried on in connection with those above noted.

"Of 54 sparrows examined in or near Princeton, coccidia were found in 43, or 80 per cent. Most of the negative cases were encountered in November and December. In the summer and fall practically all were infected. These figures agree closely with Hadley's [E. S. R., 26, p. 187] who found 79 per cent infected from May to December. Cultures of feces on agar showed that, at least in this locality, the infecting species belongs to the genus Isospora or Diplospora and not to Eimeria."

#### RURAL ENGINEERING.

Report of the superintendent of public works, Hawaii, C. R. Forbes (*Rpt. Supt. Pub. Works Hawaii*, 1916, pp. 87, figs. 15).—This report contains sections on road construction, drainage, reclamation, and sanitation projects in the islands.

Surface water supply of New Mexico, 1915, J. A. French (Santa Fe, N. Mex.: State Engin. Dept., 1915, pp. 149).—This report gives the results of measurements of flow made on streams in New Mexico during 1915, and the results of studies of evaporation from water surfaces made near Deming and Farmington, N. Mex.

Surface water supply of lower Columbia River and Pacific drainage basins in Oregon, 1914 (U. S. Geol. Survey, Water-Supply Paper 394 (1917), pp. 7-180+XLIX, pls. 2).—This report, prepared in cooperation with the States of Oregon and Washington, presents the results of measurements of flow made on streams in the lower Columbia River basin and on the Cowlitz, Rogue, Umpqua, Wilson, and Nehalem River basins during 1914.

The usual appendix on stream-gaging stations and publications relating to water resources is included.

Pump irrigation in Nebraska, E. E. Brackett and O. W. Sjogren (Nebraska Sta. Circ. 2 (1917), pp. 28, figs. 21).—This bulletin gives data on the design, installation, and cost of irrigation pumping plants including wells, with special reference to Nebraska conditions, and is based on a study of the installation and operation of pumping plants in Nebraska and other States.

A bibliography of 14 references is included.

Note on the irrigation of the Chéliff plain in the department of Oran [Algiers], Vielle (Ann. Ponts et Chaussées, 9. ser., 35 (1916), pt. 1, No. 5, pp. 166-187, flgs. 7).—This report deals with the general engineering features involved in the irrigation of an area of about 25,000 hectares (about 61,750 acres) in an Algerian dependency.

Farm drainage in Virginia, D. L. YARNELL (Dept. Agr. and Immigr. Va., Farmers' Bul. 26, pp. 30, figs. 11).—The purpose of this bulletin is to give definite information regarding methods of removing excess moisture from wet soils, with particular reference to Virginia conditions. The most space is devoted to the planning, construction, and cost of tile drains. Two brief sections

deal with the reclamation of tidal marshes and the Virginia drainage law, Fourteen references to literature bearing on the subject are appended.

[Land drainage in] Ontario, J. R. Spry (Agr. Gaz. Canada, 4 (1917), No. 3, pp. 190, 191).—Experimental tile drainage of five plats of loam soil in Ontario, Canada, was found to increase the yields of wheat, oats, barley, and hay on the average in 1916 by an amount worth \$12.44 per acre, which exceeded one-third the total cost of the drainage system. On clay soils the average increase was less, being \$4.61 per acre. No increase due to drainage of heavy clay soils was obtained during 1914, 1915, or 1916.

Institutional sewage plants, C. F. Mebus (Amer. Jour. Pub. Health, 7 (1917), No. 3, pp. 296-298).—The general requirements for the proper operation of institutional plants for the purification and disposal of sewage are outlined.

New stump burner for logged-off lands requires no blower, L. W. Allison (Engin. Rec., 75 (1917), No. 13, pp. 495, 496, fig. 1).—A new stump burner is described and illustrated.

"In contrast with the closed type of hood burner, this stump burner consists of a metal housing with various apertures for particular service, with smoke pipe connection at the top. It is constructed in sections to provide for any class of service, covering both large and small stumps.

"By the use of movable draft pipes arranged around and near the base of the burner, it eliminates the necessity for any blower or other artificial draft device, the required draft being brought about by natural conditions and hood construction, and in a highly efficient manner for the service designed. While this burner operates more slowly through the use of natural draft, demanding greater periods of time for stump consumption, the operating cost is reduced to a minimum, the primary expense being that of labor and attendance, which is low when a number of burners are in operation on the same land at the same time. . . . Recent tests on Washington timber lands show that this type of stump burner will consume stumps from 3 to 5 ft. in diameter, together with roots within the range of the burner, in a period of 24 hours, while larger stumps from 6 to 7 ft. are burned in 30 or 40 hours."

Tenth annual report of the board of county road commissioners of Wayne County [Mich.], 1916 (Ann. Rpt. Bd. Road Comrs. Wayne Co. [Mich.], 10 (1916), pp. 87, pl. 1, figs. 79).—This reports the work and expenditures of the board of road commissioners of Wayne Co., Mich., on road construction, especially concrete roads, for the year ended September 30, 1916.

First annual report of the commissioner of highways [of Oklahoma], 1915, G. B. Noble (Ann. Rpt. Comr. Highways Okla., 1 (1915), pp. 19, pl. 1).— This is a report, in manuscript, of the work and expenditures of the office of the commissioner of highways of Oklahoma on the construction, maintenance, and cost of highways in the State for the year ended December 31, 1915.

Second annual report of the state engineer [of Oklahoma], 1916, M. L. CUNNINGHAM (Ann. Rpt. State Engin Okla., 2 (1916), pp. 26).—This is a mimeographed report of the work and expenditures of the Oklahoma State engineer's office pertaining to the construction, cost, and maintenance of highways in the State during the fiscal year 1915–16 and for the calendar year 1916 up to December 1.

Annual report on highway improvement, Ontario, 1914, W. A. McLean (Ann. Rpt. Highway Improv. Ontario, 1914, pp. 223, ftgs. 68).—This report has special reference to the work of road and bridge construction carried on by the several counties of the Province of Ontario during the year 1914. It includes appendixes on county road inspection, testing of materials, nonasphaltic road oils, and traffic census statistics.

Laws of Iowa relating to roads and highways passed by the thirty-sixth general assembly, 1915, Lola S. Elliott (Des Moines, Iowa: State, 1915, pp. 28).—The text of the laws is given.

Cost of engineering an extensive county road system, W. C. Davidson (Engin. Rec., 75 (1917), No. 15, pp. 498, 499).—This article is a description of the items charged to engineering in the cost of construction of a road system in Texas consisting of 5 miles of concrete, 63 miles of water-bound macadam, and 110 miles of gravel construction and entailing the building of 488 bridges and culverts. The total cost amounted to \$1,075,000, of which 4.58 per cent was for engineering.

The results of physical tests of road building rock in 1916, including all compression tests, P. Hubbard and F. H. Jackson, Jr. (U. S. Dept. Agr. Bul. 537 (1917), pp. 23, fig. 1).—This bulletin supplements Bulletin 370 (E. S. R., 35, p. 685) and reports the results of the more common physical tests, including crushing, of 396 samples of road-building rock examined by the Office of Public Roads and Rural Engineering during 1916, as well as a complete record of all crushing-strength tests made by the Office up to January 1, 1917.

Material specifications (Ohio Highway Dept., Material Specifica, 5 (1916), pp. 80, figs. 9).—Specifications for Portland Cement, paving block, stone and slag, gravel and sand, nonbituminous binders, bituminous materials, creosoted timber, oils and paints, steel and Iron, and pipe, as prepared by the Ohio highway department, are presented, together with outlines of methods of testing.

United States Government specification for Portland cement (U. S. Dept. Com., Bur. Standards Circ. 33, 3. ed. (1917), pp. 43, figs. 10).—This specification is the result of several years' work of a joint conference representing the U. S. Government, the American Society of Civil Engineers, and the American Society for Testing Materials. It was adopted by the U. S. Government and by the American Society for Testing Materials, to become effective January 1, 1917.

Creosoting Douglas fir bridge stringers and ties without loss in strength, O. P. M. Goss (Scattle, Wash.: Assoc. Creosot. Cos. of the Pacific Coast. 1916, pp. 27, figs. 11).—This circular briefly describes Douglas fir as a structural timber, and discusses particularly a method of effectively creosoting structural forms without loss in strength. This consists essentially of boiling the timber in cresote oil under a vacuum of from 24 to 27 in.

Results of strength tests on bridge stringers and ties and of spike-pulling tests are also reported, giving information which in general should be of interest to engineers responsible for the efficient use of structural timber,

Timber framing, H. D. Dewell (West. Engin., 7 (1916), Nos. 6, pp. 209-216, figs. 2; 7, pp. 251-256, figs. 10; 8, pp. 289-298, figs. 11; 9, pp. 339-346, figs. 9; 10] pp. 385-393, figs. 13; 11, pp. 416-424, figs. 11; 12, pp. 455-461, figs. 11; 8 (1917), Nos. 1, pp. 9-17, figs. 7; 2, pp. 52-56, figs. 7; 4, pp. 132-142, figs. 7).— This is a series of ten articles on the design and construction of timber-frame structures.

Part 1 summarizes specifications for grading timber in use on the Pacific coast and discusses working-unit stresses and ultimate strengths of main members. Part 2 deals with washers and pin-connected joints and gives experimental data regarding their strength. Part 3 discusses the design of timber connections using nails, screws, lag screws, and bolts, and summarizes related experimental data. Part 4 deals with end joints of timber trusses and gives detailed computations and drawings for eight different types of joint. Part 5 discusses the complete design of intermediate joints in trusses, of tension splices, and of compression splices. Part 6 dicusses compression chords and

struts, including laminated members, timber-tension members, tension rods, and bracing trusses. Part 7 discusses the complete design of timber trusses, both of the simple and lattice type. Part 8 deals with timber columns, column connections, and joist hangers. The use of mill construction for reducing the fire risk in timber structures is also considered. Part 9 deals with timber foundations, including anchorages for columns. Part 10 discusses miscellaneous structures, including flumes, head frames, and tank towers, and also considers wind stresses and the preparation of working drawings. General specifications for timber buildings of the mill-building type are also given.

Elementary primer of electricity for light and power customers (Salem, Oreg.: Univ. Oreg., 1916, pp. 95, pl. 1, figs. 8).—This bulletin gives general information for the nontechnical reader regarding electricity and its use, and deals in some detail with the use of electricity in the home and on the farm, with special reference to Oregon conditions. A final section deals with the relation of the hydroelectric power resources to the prospective industrial development of Oregon.

Performance of two successful windmill generating plants, F. S. Culver (Elect. World, 69 (1917), No. 8, pp. 367-369, figs. 7).—This article states the considerations on which the selection of the equipment for the two plants was based, describes features of the arrangements employed, and gives the results of tests of the plants showing their ability to utilize a wide range of wind velocities.

The results of tests of the chain-driven and geared types of plant showed "that with a wind velocity of 22 miles per hour the charging rate of the geared plant had nearly reached a maximum, while with the chain-driven plant the charging current was increasing almost directly with the wind velocity. This action is due to the difference in adjustment of the differential windings of the generators. In the first case nearly the entire winding was effective, while in the other it was nearly all cut out of circuit. Thus, by adjusting the amount of the differential winding in circuit the peak charging current can be easily controlled. Another interesting fact is the low wind velocity at which the generator will charge the storage battery, current being furnished with a wind velocity of only 10 miles per hour."

Electric heating, E. A. Wilcox (San Francisco: Technical Publishing Co., 1916, pp. [VI]+286, figs. 192).—This is a semitechnical presentation of the different uses of electric heat, in which the advantages and disadvantages of various kinds of heating loads are compared and several types of heating devices explained. Data are given on the relative operating costs of electric and fuel-heated apparatus, together with suggestions regarding approved methods of installing and using domestic and commercial ranges, bake ovens, water heaters, and industrial heating devices.

More tractor evidence (Amer. Thresherman, 19 (1917), No. 11, pp. 17-19).—Tabulated data covering the operations of 59 large tractors and 37 small tractors for the past year are reported and compared with similar data for the two previous years.

Fifteen of the large tractors used gasoline and 44 used either kerosene or distillate. Among the smaller machines, 27 used gasoline and only 10 reported the use of kerosene. In the cases of 42 of the large tractors and of 30 of the small tractors, operation was cheaper than by use of horses.

"As regards tractor sentiment, 40 owners of large tractors report local sentiment favorable, as against 31 two years ago. In 12 communities the replies are unfavorable, while in the remaining 7 they either do not reply or are undecided. Out of the 37 owners of small machines, 33 reported favorable sentiment last year and only 30 this year."

The relation of horsepower to work done is shown in the following table:

Relation	of	horsepower	to	mork	in	farm	tractors.

Rating of tractors.	Area plowed in 10 hours.	Rating of tractors.	Area plowed in 10 hours.
HORSEPOWER.	Acres. 6, 30	HORSEPOWER.	Acres. 11.80
8–16	6.60	25-45	19. 20
10-20. 12-25.	7.70 9.00	3 Fa 0	21. 00 25. 75

Equipment for the farm and the farmstead, H. C. Ramsower (New York and London: Ginn & Co., 1917, pp. XII+523, figs. 543).—This is a semitechnical treatise on the subject, which contains the following chapters: Some principles of mechanics, transmission of power, materials of construction, cement and concrete, laying out the farm, farm fences, farm building, the farmhouse, lighting the farm home, sources of farm water supply, the pumping and piping of water, pumps and their operation, windmills, the hydraulic ram, power from streams, water-supply systems, sewage disposal for farm homes, the plow, tillage tools, seeding machinery, manure spreaders, haying machinery, grain binders, corn harvesters, wagons, miscellaneous tools and machines, gasoline and oil engines, and rope and its uses.

Equipment for farm sheep raising, V. O. McWhobter (U. S. Dept. Agr., Farmers' Bul. 810 (1917), pp 27, flgs. 37).—"The object of this publication is to furnish a practical guide for the equipping of farms for sheep raising. Wide differences in climatic conditions render it impracticable to suggest a particular type of building for all sections; therefore a number of types of barns and sheds are presented."

"Equipment for raising sheep on farms need not be expensive. In mild latitudes little housing is needed, and the main need is for fencing and pastures of sufficient number and size to allow frequent changing of flocks to fresh ground to insure health. Where winters are longer and more severe, buildings and sheds are necessary to furnish protection from storms, though no special provisions are needed for warmth. Dryness, good ventilation, and freedom from drafts are the first requisites of buildings for sheep. Convenience in feeding and shepherding must also be held in mind in locating and planning such buildings or sheds. Small flocks can be cared for in sections of barns having stabling or feed storage for other stock, but with a flock of, say, 100 ewes separate buildings are desirable. The interior arrangement of these buildings should be such as to require a minimum of labor and the least possible moving of the ewes in doing the feeding and caring for them during the lambing season. A building of this type can also be utilized for fattening purchased lambs to be disposed of before lambing begins in the regular farm flock. A good supply of feed racks, grain troughs, etc., can be provided at small expense and will save labor and prevent waste of feed."

Fencing, crates, feed racks, and miscellaneous equipment are also described. Municipal piggeries, O. A. Bridges (Surveyor, 51 (1917), No. 1315, pp. 322, 323, figs. 4).—This article gives plans and a brief description of hog houses for municipal use, these being advocated as a war-time measure in England.

Pit, semipit, and bank silos, L. W. Chase (Nebr. Col. Agr., Ext. Serv. Bul. 39 (1917), pp. 16, figs. 19).—This bulletin gives information on the construction and cost of pit, semipit, and bank silos in Nebraska. It is stated that the

bank silo is the most convenient and most expensive, while the pit silo is the cheapest and least convenient.

Poultry house construction, K. J. T. EKBLAW (Nat. Lumber Manfrs. Assoc., Trade Ext. Dept. Farm Bul. 5 (1916), pp. \$\overline{2}1\$, figs. 8).—This bulletin deals with the general requirements, construction, and equipment of poultry houses, and includes several diagrammatic illustrations.

### RURAL ECONOMICS.

[Report of the sixth annual meeting of the American Farm Management Association] (Amer. Farm Management Assoc. Rpt., 6 (1915), pp. 91, pl. 1, figs. 4).—Among the papers presented at this meeting were the following: What the Future Holds in Farm Management, by A. Boss; Land Credits and Land Settlements, by T. F. Hunt; Utilization of Waste on the Farms, by W. S. A. Smith; Results of Farm Management Demonstration Work, by L. H. Goddard; Gaining a Foothold on the Land, by E. H. Thomson; Farm Management Summer Practice Courses, by R. L. Adams; The Practical Application of Farm Management Principles, by H. W. Jeffers; The Farmer's Response to Economic Forces, by W. J. Spillman; and Farm Management Investigations in Minnesota, by F. W. Peck.

Validity of the survey method of research, W. J. SPILLMAN (U. S. Dept. Agr. Bul. 529 (1917), pp. 15).—The author cites numerous comparisons of farmers' estimates with actual records, and states that "our studies lead to the conclusion that errors in the farmer's knowledge of the details of his business and of the work he does are in every way comparable to the departures from the true means in field plat experimental work, and that they distribute themselves about the true values in approximately the same manner. The fact that the survey method of investigation gives data sufficient to permit the law of averages to eliminate plus errors by the occurrence of similar minus errors, while plat experiments ordinarily do not do this, appears to justify the statement that the survey method is a more reliable means of arriving at those facts to which it is applicable than the field plat experimental method. It appears, in fact, to occupy a place intermediate between plat experiments on the one hand, where variations in other factors than that under observation occur and are not adequately eliminated, and laboratory studies on the other hand, in which variations in other factors are largely prevented. These variations due to factors other than that studied do occur in using the survey method, but the amount of data obtained by this method is sufficient to permit the elimination of such variations by the operation of the law of averages."

Agriculture and preparedness, H. Myrick (New York: Orange Judd Co., 1917, pp. 67).—Among the various means that may be used to put agriculture on a better basis are suggested easier means of distributing agricultural products, increased use of the Federal Farm Loan Act, a provision for short-time credit, the stimulating of saving and thrift among the American people, and the securing of an abundant labor supply through the revision of our immigration laws.

he relation of production to consumption, P. J. DUTOIT (So. African Jour. Sci., 13 (1916), No. 4, pp. 132-139).—The author points out that the condition of both the consumer and producer can be improved by an enlargement of the consuming power as well as the producing power. This can proceed in South Africa along three lines, namely, (1) natural increase of population, (2) increase of, or new, demand beyond their boundaries, and (3) stimulation of the wants of the native population.

Solving the food problem, A. M. Soule (Ga. State Col. Agr. Bul. 124 (1917), pp. 13).—The author has indicated the quantity of food necessary to maintain an adult and an average family, the acreage of crops and the number of animals necessary to produce this food, and the best methods of planting the various crops.

Plantation farming in the United States (Bur. of the Census [U. S.], Plantation Farming in U. S., 1916, pp. 40, flgs. 37).—The Bureau of the Census has defined a plantation as a "continuous tract of land of considerable area under the general supervision or control of a single individual or firm, all or a part of such tract being divided into at least five smaller tracts, which are leased to tenants." This report gives details regarding the number of such plantations, the total and improved acreage, and the value of land and buildings. Special data are also given for the Southern States, covering altogether 325 counties.

Farms for sale or rent in New York, 1917, C. W. LARMON (N. Y. Dept. Agr. Bul. 90 (1917), pp. 179, pls. 63).—This bulletin brings up to date for 1917 the list previously noted (E. S. R., 35, p 589).

Land settlement, C. Tubnor (In Labor, Finance, and the War, London: Sir Isaac Pitman & Sons, Ltd., [1916], pp. 329-342).—The author points out that to increase the output of food Great Britain must raise the standard of cultivation of all the average farmers, guarantee a remunerative price for home-grown food, check as far as possible great fluctuations in prices, improve marketing conditions by organization, lay it down as essential to the safety and welfare of the country that certain definite quantities of the chief articles of food must be produced at home, and increase the agricultural population by securing to the laborer a reasonable living wage, providing a sufficient supply of good cottages, and making village life more attractive. With these considerations as a basis, he advises the creation of a land-settlement board to control all settlement in the United Kingdom, and provide that small holdings should be placed on reclaimed land, land bought in open market or acquired when existing tenants give up their farms, land taken from excessively large farms, and land so situated near new plantations that the new settler would be provided with a dual occupation as forester and cultivator.

Causes of rural migration, J. Simonot (Vie Agr. et Rurale, 7 (1917), No. 13, pp. 217-221).—Among the causes mentioned are the limiting of the size of the family because of the size of the income and housing conditions. It is suggested that improvement could be obtained through agricultural instruction and the breaking up of the larger sized farms.

Seasonal distribution of farm labor in Chester County, Pa., G. A. BILLINGS (U. S. Dept. Agr. Bul. 528 (1917), pp. 29, figs. 3).—The region studied for this investigation "includes the region already covered by a farm-management survey made by this Department (E. S. R., 34, p. 592), and, in addition, areas outside of this area having similar agricultural conditions." The farmers selected were 165 who received more than the average net income. A description is given of the periods of performing the various field operations in connection with the more important farm crops, with data showing the various operations with the usual crew of men and horses, acres covered in a 10-hour day, as well as days per acre. With these data as a basis, the author outlines how a typical farm may be reorganized to make a more efficient utilization of its horse and man labor.

Marketing live stock in the South: Suggestions for improvement, S. W. Doty (U. S. Dept. Agr., Farmers' Bul. 809 (1917), pp. 16).—The author reports that the prevailing methods of marketing live stock in Tennessee, North Caro-

lina, South Carolina, Georgia, Florida, Louisiana, Mississippi, Alabama, and Arkansas are as follows:

Relative use of various methods of marketing live stock in the nine Southeastern States.

Kind of live stock.	Sold to local butchers. on foot.	Sold as farm- dressed carcasses.	Sold to local dealer- shippers for ship- ment to market.	Shipped by owners in car lots.	Miscel- laneous.
Cattle	Per cent. 38 50 43 54	Per cent. 9 6 12 16	Per cent. 36 35 30 17	Per cent. 7	Per cent. 10 9 15

The author describes the various marketing systems that are being used in the South, such as the local marketing of stock on foot, cooperative live-stock shipping associations, Tennessee lamb and wool marketing clubs, the cattle-sales system of South Carolina, the marketing of farm-cured meats, the establishment of ice plants to facilitate the storing and marketing of meats, and the public abattoir. He points out that the farmer should study the requirements of the market in order that he may make his offerings in the best form.

Report of the superintendent of the territorial marketing division to the governor of the Territory of Hawaii, for the period ending December 31, 1916, A. T. Longley (Honolulu: Mercantile Printing Co., Ltd., 1917, pp. 15).— The author reports the amount of business done by the Hawaii Marketing Division and new work undertaken during the year, and makes recommendations for the expansion of the marketing equipment.

Market distribution of poultry products, E. W. Benjamin (N. Y. Dept. Agr. Bul. 86 (1916), pp. 2380-2386).—The author outlines methods that may be used in organizing farmers for the sale of their poultry, as gained from his experience with the Poultry Producers Association of Ithaca, N. Y.

Marketing, B. Adams (N. Y. Dept. Agr. Bul. 86 (1916), pp. 2311-2320).— The author believes that marketing of farm products could be carried on to better advantage by a thorough understanding of the consumer's desires, the standardization of the products, and better organization at the producer's end.

Marketing and farm credits (Nat. Conf. Marketing and Farm Credits, 4 (1916), pp. XII+546).—This is the report of the fourth National Conference on Marketing and Farm Credits, held at Chicago, December 4-9, 1916. It contains papers on the subjects of the Federal Farm Loan Act and personal credit land settlement and immigration, marketing of live stock, marketing of grain and cheese, and the organization of agriculture.

Suggestions from America for cooperative selling, A. W. Ashby (Jour. Bd. Agr. [London], 22 (1915), No. 3, pp. 201-210, pl. 1, figs. 2).—The author discusses the marketing organizations, and packing, marking, use of brand, and advertising as practiced by the various agricultural organizations in the United States.

The organization and management of a farmers' mutual fire insurance company, V. N. Valgren (U. S. Dept. Agr. Bul. 530 (1917), pp. 34, fig. 2).—
The author discusses the ideal purpose of such a company, the business territory, the membership and voters' privileges, the officers, methods of conducting the inspection, the form and terms of policy, the liability of the company and of

the insured, fees and assessments, etc. He also includes model articles of incorporation, and suggestions for organization and business forms.

[Cooperation in Switzerland] (Pubs. Sec. Paysans Suisses, No. 55 (1916), pp. 95).—This is the nineteenth annual report of the Swiss Agricultural Society (E. S. R., 33, p. 394).

Monthly crop report (U. S. Dept. Agr., Mo. Crop Rpt., 3 (1917). No. 5, pp. 37-44).—This report contains the usual statistical data relating to the summary of farm prices, crop conditions on May 1 for winter wheat, rye, and hay, and the condition of spring pasture, spring plowing, and spring planting, the estimated farm value of important products, and the range of prices of agricultural products at important markets. It also contains special articles regarding the efficiency of agricultural workers in the United States and European countries, yearly summaries of world production of important crops, materials used to make alcoholic liquors in the United States, export of food products, index numbers of prices of meat animals, and index number of the combined price of 10 important crops. There is also a special report on commercial acreage and production of strawberries, the honeybee, crop conditions in California and Florida, production of maple sugar and sirup, beet-sugar production, and the 1916 Louisiana sugar crop, as well as miscellaneous data.

[Trade and commerce in agricultural products in Chicago, 1916] (Ann. Rpt. Bd. Trade Chicago, 59 (1916), pp. XXXV+194+141).—This report continues data previously noted (E. S. R., 35, p. 497), adding data for the following year.

The agricultural output of Great Britain (London: Bd. Agr. and Fisheries, 1912, pp. 62).—This is the report made by the Board of Agriculture and Fisheries in connection with the Census of Production Act of 1906, relating to the total output of agricultural land, the number of persons engaged, and the motive power employed. The discussion in this report is amplified by a large number of statistical tables, giving data in detail regarding the items mentioned.

Returns of produce of crops in England and Wales, A. W. ANSTRUTHER (Bd. Agr. and Fisheries [London], Agr. Statis., 51 (1916), No. 2, pp. 37-59).—This publication continues data previously noted (E. S. R., 35, p. 893).

Acreage and live stock returns of Scotland, J. M. RAMSAY (Agr. Statis. Scotland, 4 (1915), pt. 1, pp. 55).—This report continues data previously noted (E. S. R., 35, p. 497).

[Agricultural statistics of Denmark] (Statis. Aarbog. Danmark, 21 (1916), pp. 40-62).—This yearbook contains information along the lines previously noted (E. S. R., 34, p. 792), adding data for the crop year 1916.

#### AGRICULTURAL EDUCATION.

Agricultural education, A. C. Monahan and C. H. Lane (Rpt. Comr. Ed. [U. S.], 1915-16, I, pp. 237-258).—This is a review of progress in agricultural instruction in secondary schools; a discussion of the question of the administration of boys' and girls' agricultural club work in the various States, i. e., whether as a function of the State department of education or of the State agricultural college, and if in the college, whether in the department of agricultural extension teaching or in the department of agricultural education; A State System of Agricultural Education, by K. L. Butterfield, previously noted (E. S. R., 36, p. 93); agricultural education at meetings of the year; educational work of the U. S. Department of Agriculture through its States relations Service and the Forest Service; and the principal developments of agricultural education in foreign countries.

According to the report, 2,175 high schools are teaching agriculture to a total of 41,055 boys and girls. Of these schools, 19 were established before 1901, 33 from 1901 to 1905, 413 from 1906 to 1910, and the remainder since 1910. The teaching of agriculture as an informational subject is reported by 1,521 high schools, and as a vocational subject by 506. Of 2,254 persons teaching agriculture, 1,021 have special training in the subject, varying from a four-year agricultural course to a summer course. School land for instructional purposes is used by 392 schools, 337 schools are teaching through the home-project method, 416 give classroom instruction only, and 1,064 give classroom instruction with laboratory exercises and observation of neighboring farms.

There are also 68 special secondary schools supported in whole or in part by the State, with a total cost of maintenance of \$766,000, and a total of 416 teachers, and 1,079 elementary and 6,301 secondary pupils. Special schools of agriculture are maintained in connection with ten of the State colleges of agriculture on the college campus, and agricultural courses of secondary grade are given to special students in 20 other State colleges of agriculture.

Rural and agricultural education at the Panama-Pacific International Exposition, H. W. Foght (U. S. Bur. Ed. Bul. 2 (1916), pp. 112, figs. 82).—This bulletin deals with the educational exhibits at the Panama-Pacific Exposition of 1915, which were prepared to indicate recent progress in rural life and education. It discusses (1) government exhibits illustrating the organization and work of the U.S. Bureau of Education, the proposed plan of Federal aid for vocational education, progress in negro education, the promotion of school health, rural school progress by means of miniatures of school grounds and buildings, organization of agricultural education in the United States, and the activities of State agricultural colleges and experiment stations; (2) State educational exhibits, illustrating the improvement of the one-teacher school through standardization and vitalization of school activities by means of industrial club work, the establishment of effective farm community schools by means of school consolidation and organization of rural high schools, and the organization of State wide, State aided agricultural extension work through special schools and special agricultural projects; (3) rural education in the territories and insular possessions; and (4) exhibits of public and private agencies. The exhibit material consisted of mounted graphic charts, maps, photographs, transparencies, samples, specimens, miniature models, publications, stereomotographs, moving pictures, and moving hexagonal cylinders.

Report on the work of the Bureau of Education for the natives of Alaska, 1914-15 (U. S. Bur. Ed. Bul. 47 (1916), pp. 85, pls. 18).—This bulletin contains, among other material, reports by teachers in the public schools under the control of the Federal Government, including notes on instruction in gardening, cooking, sewing, laundering, hygiene, sanitation, etc.

Home economics, Henrietta W. Calvin and Carrie A. Lyford (*Rpt. Comr. Ed. [U. S.]*, 1915-16, I, pp. 271-288).—This annual review deals with the importance of home economics in recent educational surveys, home economics instruction in colleges, universities, normal schools, and public schools, the conference of home economics teachers employed in land-grant colleges, cafeterias and lunch rooms, hot lunches in rural schools, practice cottages, home economics in colored schools, home economics associations, and extension teaching.

The authors find that while there has been a steady increase in the number of schools offering instruction in home economics and in the length of courses, the most marked advance has been in the type of course offered, in the standards of instruction that have been established, and in the effort to relate the instruction to home life and conditions. In their opinion, schools of education

and systems of city supervision are going to be the most potent factors in the development of educational methods in home economics, while colleges and universities are developing the subject matter in its scientific and economic relationship, strengthening their teacher-training courses, and installing courses for the preparation of extension teachers.

Elementary agricultural instruction, M. B. SMITS (Teysmannia, 27 (1916), No. 9-10, pp. 524-549).—The author briefly discusses the organization of agricultural instruction in Holland, Hungary, South Africa, Argentina, Ceylon, German East Africa, the Philippines, and the Dutch East Indies, with suggestions for the improvement of that in the country last named.

Report of the commissioner of industrial and vocational education, E. R. SNYDER ([Bien] Rpt. Comr. Indus. and Vocational Ed. Cal., 1915-16, pp. 98).— This report contains statistical data with reference to courses in manual and industrial arts, household arts, commercial training, and agriculture. This includes the date of introduction of the course, its length, and the grades to which it is open, the experience and certification of the teachers, practical work, subjects of instruction, and the character of the course (whether prevocational, preparatory, cultural or disciplinary, vocational, or strictly supplementary to a vocation) in California day high schools, intermediate day schools with a ninth grade, secondary evening schools, elementary city schools with grades above the sixth, and elementary rural schools with six or more teachers. The statistics are discussed, and suggestions and recommendations presented.

Schools of agriculture, mechanic arts, and home making, L. S. Hawkins (Univ. State N. Y. Bul. 626 (1916), pp. 27, pls. 5, figs. 6).—Information is given with reference to the two types of schools of agriculture, mechanic arts, and home making, in New York, including the procedure in organizing them, qualifications of teachers, curriculums and courses of study, summer work for the teacher of agriculture, the use of land (including project work), and rooms and equipment, in accordance with the vocational education law, the text of which is given, and the rules and regulations of the University of the State of New York.

Rural education associations and their activities (Saskatchewan Dept. Ed., School Agr. Circ. 7 (1917), pp. 16).—This circular contains a history of the movement, the chief object of which is to arose public interest in rural life generally and agricultural education particularly; suggestions for work of an association, including the organization of boys' and girls' agricultural and home economics clubs, of projects for school garden work and competitions, of boy scout troops and girl guide troops who undertake nature study work, and of school fairs and social service work; a constitution for the organization of an association; and a list of associations, with a summary of their activities. There are at present 40 rural education associations in Saskatchewan.

Some problems in the organization and administration of a department of poultry husbandry at a secondary school of agriculture, L. Banta (Jour. Amer. Assoc. Instr. and Invest. Poultry Husb., 3 (1917), No. 6, pp. 41-43).— The author points out a few of the problems that have come up for solution during a year of instruction in poultry husbandry at a secondary school. They include the task of defining the scope and limitations of this work, the equipment, the extent of experimentation and of elective, specialized courses in addition to the usual fundamental and elementary ones, pedagogical training of college-trained instructors, lack of interest in some localities, lack of sufficient fundamental scientific preparation on the part of students, the pedagogical importance of the lecture and recitation, entrance requirements, practical experience of students, college entrance credit, etc.

How we can attain greater efficiency in laboratory instruction? R. F. Irvin (Jour. Amer. Assoc. Instr. and Invest. Poultry Husb., 3 (1917), No. 6, pp. 45-47).—In discussing the problems involved in laboratory instruction in poultry husbandry in the college, the author suggests that each course should first be outlined in syllabus form, lecture, recitation, and laboratory exercises being correlated. This should be followed by a standard laboratory plan or laboratory exercise sheet, which should include as essential features the title of the exercise, object of the exercise, apparatus and equipment needed, method of procedure, leading questions, and conclusions. It is claimed that laboratory instruction on such an organized basis would enable the instructor to utilize every minute of the laboratory period to the best advantage. Suggested outlines are given of model laboratory sheets on a study of the 60-hour embryo and the sticking and dry picking of market poultry.

Gardening in elementary city schools, C. D. Jarvis (U. S. Bur. Ed. Bul. 40 (1916), pp. 74, pls. 3, figs. 4).—In this bulletin the author attempts to show briefly how productive gardening contributes to the needs of the school, as in democratizing education, supplying a long-felt need in vocational guidance and a substitute for hurtful child labor, developing thrift and industry, furnishing recreation, improving health and morals, uniting the home and the school, etc. He discusses the kinds of gardens, their control, instruction, supervision, and financing, and outlines a suggestive program for the promotion of gardening by schools employing the home garden method in its broadest sense. This includes gardening on the school grounds where it forms a part of the home garden system and where the individual plats are regarded as home gardens or independent projects. The program includes a preliminary survey, procuring land, the selection of crops, planning the garden, outside and classroom instruction, disposing of the crop, keeping records, and means of arousing and maintaining interest.

A course in nature study and agriculture, W. T. SKILLING (Bul. State Normal School, San Diego, Cal., 3 (1915), No. 3, pp. 8).—This is an outline of the course in nature study and agriculture, with suggestions for work in the model and training school, of the State Normal School at San Diego, Cal.

Courses in secondary agriculture for southern schools (first and second years), H. P. Barrows (U. S. Dept. Agr. Bul. 521 (1917), pp. 53).—These outlines, covering work in agriculture for the first two years of a 4-year course, have been prepared to meet a demand for a more uniform standard in agicultural instruction in secondary schools in the South. They are based on work in nature study and a general course in elementary agriculture in the graded or rural school. The outline for the first year covers lessons and practical exercises in soils and field crops, and for the second year, lessons and practicums in animal busbandry. Suggestions for home projects, equipment, distribution of time and credit, etc., and lists of texts and references are included.

Suggested experiments in elementary plant physiology, L. H. Pennington (Syracuse Univ. [Pubs.], 17 (1917), No. 30, pp. 46).—This is a series of laboratory experiments and exercises to illustrate the fundamental scientific facts and theories underlying elementary plant physiology, arranged especially for students in forestry at the New York State College of Forestry.

Ferm spies, A. F. Conradi and W. A. Thomas (New York: The Macmillan Co., 1916, pp. XI+165, figs. 67).—This book deals with the facts concerning the life history and habits of the boll weevil, the black billbug and budworm of corn, the black corn weevil, grasshoppers, chinch bugs, the cotton root louse, and the larger cornstalk borer, and methods of controlling them. It is written in story form for boys and girls.

Food study, Mabel T. Wellman (Boston: Little, Brown and Co., 1917, pp. XXIV+324, pls. 8, figs. 38).—This text in home economics for high schools consists of a study of the principles involved in cooking, the economic and dietary value of foodstuffs, their care and preservation, the origin of various food plants, and the manufacture of food products. The instruction given from an inductive standpoint consists of classroom cooking and experiments. Food requirements for adults, tables of height and weight and of fuel values, and a list of supplementary laboratory lessons are appended.

Illustrated lecture on practical improvement of farm grounds, F. L. Mulford and H. M. Conolly (U. S. Dept. Agr., States Relat. Serv. Syllabus 28 (1917), pp. 13).—Suggestions are given with reference to the location, exposure, and type of house; location of barns; the size, arrangement, and care of grounds; walke and drives; entrances; the lawn; plan of the grounds; and where, what, when, and how to plant, and cost of planting, in order to make the farm-home grounds attractive and interesting. A list of 51 lantern slides to illustrate the syllabus and a brief list of references to literature on the subject are appended.

#### MISCELLANEOUS.

Abstracts of papers not included in bulletins, finances, metereology, index (Maine Sta. Bul. 257 (1916), pp. 343-367+XII).—This contains the organization list of the station; abstracts of 6 papers published elsewhere and previously noted, and abstracts of 3 papers noted elsewhere in this issue; meteorological observations noted on page 314; a financial statement for the fiscal year ended June 30, 1916; an index to Bulletins 246 to 257, inclusive, which collectively constitute the thirty-second report of the station; and announcements as to the work, publications, and equipment of the station.

Director's report for 1916, W. H. JORDAN (New York State Sta. Bul. 428 (1916), pp. 529-558).—This contains the organization list and a review of the work and publications of the station during the year.

Twenty-sixth Annual Report of Wyoming Station, 1916 (Wyoming Sta. Rpt. 1916, pp. 61-100).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1916, reports of the acting director and heads of departments, of which that of the parasitologist is abstracted on page 374 of this issue, and meteorological observations noted on page 314.

Monthly Bulletin of the Ohio Experiment Station (Mo. Bul. Ohio Sta., 2 (1917), No. 5, pp. 137-171, figs. 11).—This contains several articles abstracted elsewhere in this issue, together with the following: The Soy-bean crop, by C. G. Williams, adapted from Bulletin 312 (E. S. R., 37, p. 235); The Lesser Peach Tree Borer, by J. L. King, an abstract of Bulletin 307 (E. S. R., 37, p. 159); More Corn to the Acre, by C. E. Thorne; and Notes.

# NOTES.

Delaware College and Station.—Wolf Hall, the new \$280,000 building which will house all the activities of the agricultural department and temporarily the college departments of chemistry and biology, is practically completed and will be occupied in September.

Frank A. Hays, Ph. D. (Iowa State College, 1917), has been appointed assistant professor of animal husbandry. Mark L. Nichols, assistant professor of agronomy and assistant agronomist, and Raymond R. Pailthorp, assistant professor of horticulture and assistant horticulturist, have been transferred entirely from station to college work.

Idaho University and Station.—Appropriations made by the last legislature for the station for the present biennium are as follows: For the further study of insect pests troublesome to alfalfa and clover seed producers, \$4,000; for emergency calls in the investigation of plant diseases, insect pests, and soil troubles, \$1,200; for soil survey work in cooperation with the Bureau of Soils, U. S. Department of Agriculture, \$1,200; for the erection of additional greenhouses, \$4,500; and for tile-draining a portion of the university farm and fencing the farm, \$2,500. In addition, the Aberdeen substation received \$5,000, that at Caldwell \$7,800, and that at Sandpoint \$5,000.

The segregation of 160 acres of State lands was authorized for use in a study of problems concerned with high altitude agriculture. A substation, to be known as the high altitude substation, is to be established in a region whose altitude is 6,000 feet or more. An appropriation of \$3,500 is made for the biennium, and the citizens of the community in which it is located are obligated to raise a like amount for the erection of buildings.

The irrigation work of the station has been transferred from Gooding to Caldwell. This transfer was made necessary by the approaching expiration of the lease under which the Gooding substation has been operated since 1909, and the resignation of Superintendent J. S. Welch, who is now connected with the Maori Agricultural College of New Zealand.

From a State appropriation made for the erection of new buildings at the university, the State Board of Education has authorized the use of \$25,000 for the erection of a new horse barn, hog and sheep barns, and a seed house. The completion of the south wing of the university administration building and the erection of an annex to the engineering building have also been authorized.

Dr. Ernest H. Lindley, professor of philosophy at the University of Indiana since 1902, has been appointed president, succeeding Dr. M. A. Brannon, who became president of Beloit College on July 1. Dr. C. H. Shattuck, professor of forestry and forester, resigned June 30. Dr. A. R. Hahner, instructor in veterinary science, resigned last April and has been succeeded temporarily by Dr. H. C. Luce. Other appointments include H. W. Hulbert as instructor and assistant in farm crops, and A. C. Baltzer as instructor in dairy husbandry and assistant dairy husbandman,

New members of the governing board include William Healy of Boise, J. A. Lippincott of Idaho City, and J. A. Keefer of Shoshone.

Kentucky University and Station.—Dr. Robert Graham, professor of veterinary science and head of the department of diseases of live stock in the station, has been appointed professor of animal pathology and chief of animal pathology in the Illinois University and Station. Dr. C. D. Bohannan, associate professor of agricultural economics, R. C. Dabney, connected with the inspection of bakery sanitation, R. B. Taylor, assistant chemist in the fertilizer department, and J. T. Milligan, in charge of the egg laying contest, have resigned.

Minnesota University and Station.—A modern structure is to replace in the near future the old stock barn which was recently burned. This building will be of reinforced concrete and hollow tile, with the upper portion of frame and stucco. A new seed house is also to be erected.

R. W. Thatcher has been appointed dean of the department of agriculture and director of the station. Dr. E. M. Freeman has been appointed dean of the college of agriculture within the department.

Dr. R. A. Gortner, associate professor of biochemistry, has been appointed professor in this subject and chief of the division in the college and station. R. A. Dutcher, assistant professor of agricultural chemistry at the Oregon College, and C. A. Morrow, professor of chemistry in the Nebraska Wesleyan University, have been appointed assistant professors of agricultural biochemistry, effective September 15. S. D. Wilkins and V. C. Crowl have been appointed assistants in the division of animal nutrition; A. J. Wuertz, assistant in agricultural biochemistry, and J. E. Chapman, assistant in soils.

C. W. Howard, associate professor of economic entomology and assistant entomologist, has resigned to become professor of biology in Canton Christian College, China. W. F. Lusk, assistant professor of agricultural education, has accepted a similar appointment in Cornell University, and John Parker a position in agronomy in the Kansas College. Miss Ferne Peck, instructor in agricultural botany and seed analyst, has been appointed State seed analyst in Nebraska, and has been succeeded by A. H. Larson.

Leave of absence for six months has been granted to Miss Josephine T. Berry, chief of the division of home economics, to become assistant director of vocational education and director of home economics with the Federal Vocational Education Board, and for one year to Miss Grace I. Williams, assistant professor of home economics, for graduate study. Miss Anna E. Bayha and Miss Olive N. Tuttle have resigned as instructors in home economics.

W. L. Oswald, assistant professor of agricultural botany and assistant botanist and plant pathologist, has accepted an appointment with the Bureau of Markets of the U. S. Department of Agriculture to assist in a survey of the seed situation. Francis Jager, chief of the division of apiculture, has been appointed a member of the Red Cross mission to Serbia. Miss Alice McFeely has been appointed assistant editor of station bulletins.

At Crookston, T. R. Sewall, superintendent of buildings and grounds, and Mrs. T. R. Sewall, instructor in domestic science, resigned July 31. Miss Hazel Rockwood, a 1917 graduate of the college, has been appointed instructor in home economics, and A. M. Folker instructor in farm engineering and superintendent of buildings and grounds.

Missouri University and Station.—A new position has been established in the extension work, known as the woman county home demonstration agent. Demonstrations are to be conducted cooperatively by the agricultural extension service, the U. S. Department of Agriculture, and the county. Each county is

required to appropriate not less than \$500 for the support of the agent, while the university will contribute not more than \$750 a year for salary and maintenance.

Leaves of absence have been granted Howard Hackedorn, assistant professor of animal husbandry, and C. R. Moulton, assistant professor of agricultural chemistry, for a year's graduate work, and to E. M. McDonald, assistant professor of farm crops, who has entered a reserve officers' training camp. Resignations have been accepted of Roy Hastings, assistant in agricultural extension; Thomas M. Olson, agricultural agent for Butler County; Chester Pollock, dairy cattle herdsman; Walter E. Thrun, assistant in agricultural chemistry; and Willis B. Combs, assistant in dairy husbandry.

Recent appointments include the following: Carl Marsh, dairy cattle herdsman; J. A. Machliss, assistant in soil survey; L. W. Morley, assistant in dairy husbandry; Paul M. Robinett, assistant in horticulture; Sarah Pettit, superintendent of women's county home demonstration work; Edward A. Livesay, assistant county agent leader; John T. Stinson, assistant in agricultural extension; E. Roy Keller, assistant in boys' and girls' club work; Mary E. Robinson, extension instructor in home economics; and Dr. F. W. Caldwell, extension assistant professor of veterinary science.

North Dakota College.—H. L. White, professor of physiological chemistry and toxicology, has been appointed professor of biological chemistry in the college of physicians and surgeons of the University of Southern California.

Oklahoma College and Station.—The station has recently completed a modern two-story grain storage house. The upper story will be used for laboratory work in plant breeding, seed selection, etc. The lower floor has six rooms, three of them designed for storage rooms for small grains and equipped with special appliances for fumigation, and the remainder are designed for a general receiving and work room, a machine room for the graders, ginners, etc., and a general storage room, respectively.

The station reports the resignation of Dr. C. K. Francis, chemist, B. A. Ahrens, poultry husbandman and head of the poultry department, Henry L. Thomson, head of the farm engineering department, and W. L. Fowler, animal husbandman and head of the animal husbandry department. Harry Embleton has been appointed professor of poultry husbandry and poultryman, and Dr. Wallace Macfarlane has been transferred from assistant agronomist to station chemist. Dr. L. L. Lewis, veterinarian and bacteriologist of the station and dean of the veterinary school, has been granted six months' leave of absence on account of ill health.

Oregon College and Station.—Roy R. Graves, professor of dairying and dairyman, has resigned to accept a position with the Dairy Division of the U. S. Department of Agriculture. A. F. Kerr, of the Forest Service, has been appointed instructor of forestry. O. D. Center, director of extension of the University of Idaho, has been appointed director of extension to succeed R. D. Hetzel, whose resignation has been previously noted.

Wyoming University.—Dr. Aven Nelson, professor of botany, has been appointed acting president.

Federal Food Control Act.—This elaborate war measure was signed by President Wilson, August 10. Its object is expressed in the opening section as "to assure an adequate supply and equitable distribution, and to facilitate the movement, of foods, feeds, fuel including fuel oil and natural gas, and fertilizer and fertilizer ingredients, tools, utensils, implements, machinery, and equipment required for the actual production of foods, feeds, and fuel, hereafter in this act called necessaries; to prevent, locally or generally, scarcity,

monopolization, hoarding, injurious speculation, manipulations, and private controls, affecting such supply, distribution, and movement; and to establish and maintain governmental control of such necessaries during the war."

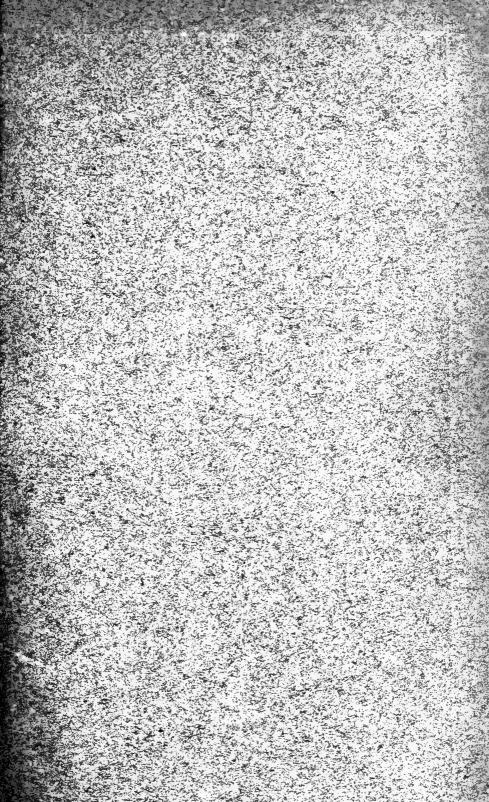

The act confers greatly extended powers upon the President during the existence of a state of war and imposes drastic penalities for violation of its provisions. Many of these powers deal with the control and distribution of food as well as a number of other commodities. In administering the act, the President is authorized to use any Department or agency of the Government, as well as to establish and work with other agencies. The enforcement of the provisions relating to the control and distribution of foods has been entrusted by him to Herbert Hoover, appointed Food Administrator.

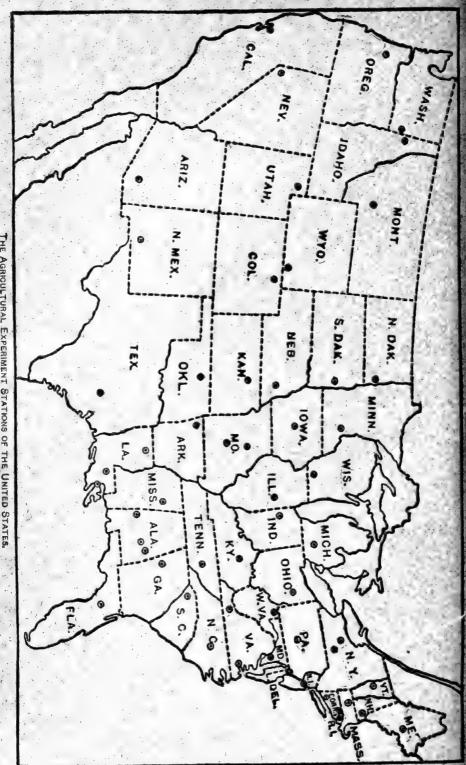

Among practices specifically prohibited in the act are the wilful destruction of necessaries for the purpose of enhancing the price or restricting the supply, conspiring to restrict their production or manufacture for the same purposes, and to hold or attempt to monopolize necessaries as defined in the act. A system of licensing various operations is authorized when deemed essential, and the President under certain conditions may seize factories, packinghouses, or other plants and operate them. He may requisition foods, feeds, fuels, and other supplies needed by the Army or Navy, and may purchase, store, and sell to the public wheat, flour, meal, beans, and potatoes, as well as procure nitrate of soda to sell at cost if the emergency requires it and it is possible to secure the material. In an emergency requiring stimulation of wheat production, he may fix a minimum guarantied price. For the crop of 1918 this guaranty is made absolute until May 1, 1919, and is fixed at not less than \$2.00 per bushel for No. 1 northern spring wheat or its equivalent at the principal interior markets.

The use of foods, fruits, food materials, or feeds for the production of distilled spirits for beverage purposes is prohibited after September 8, 1917. The President is also empowered to restrict or prohibit the use of these materials for the production of malt or vinous liquors if deemed essential to the food supply or the national security and defense.

An appropriation of \$152,500,000 is provided for the enforcement of the act, with \$10,000.000 additional for the purchase of nitrate of soda.

Food Training Camps at Agricultural Fairs.—A recent article in Breeder's Gazette outlines plans adopted by the American Association of Fairs and Expositions for cooperating with the Government in conserving the food supply through emergency food conservation exhibits and demonstrations. These plans include the use of standardized exhibits dealing especially with wheat substitutes, the conservation of fats and milk, and the home canning, drying, etc., of fruits and vegetables. The boys' and girls' clubs are expected to furnish demonstrations of these and other desirable practices, and the U. S. Department of Agriculture, the Food Administration, and the Council of National Defense are among the many agencies actively cooperating.

# EXPERIMENT STATION RECORD.

Vol. 37.

**OCTOBER**, 1917.

No. 5.

The great importance to the national welfare of research and education in agriculture has been given striking illustration at this time. It has been made apparent that the foundation of our present agricultural preparedness—the thing which makes it possible to invoke and stimulate more intensive and more highly effective production, is the existence of a vast fund of reliable information resting on a sound scientific basis. It is the product of research and experiment, seconded by teaching to inculcate it and make it more broadly known. It is seen that this foundation was being laid in the past decades by long and patient effort, and in large measure is now ready for use at the time it is needed. The result is a tribute to the agencies concerned. The time has brought enlarged recognition of their services and their inherent possibilities.

In this country, as well as in the warring countries of Europe, the present emergency has forced home as nothing else could, the dependence of power and resourcefulness upon the progress of science through investigation, and the development of men and institutions for it. Research in general has been given a great impetus and a new understanding. Its indispensability to the national welfare as a means of progress has been vastly emphasized, and its place will continue to be magnified after the war.

Everyone familiar with the process by which knowledge is advanced realizes that it is a relatively slow operation and can rarely be hurried. The general public has not always understood this. The actually new and fundamental facts which can be worked out in time to serve a sudden emergency are quite limited, but with a broad scientific basis of facts and principles to draw upon, profitable suggestion may become fertile in devising improvements and economies of various kinds which are effective in meeting special conditions. This is now being done in agriculture and is the large contribution of science in aiding the present situation.

The lesson has been taught that research can not be carried on spasmodically under stress of temporary emergency, but must go forward continuously, year in and year out, from generation to

generation. And it must be surrounded by conditions in which it will best thrive, without the handicap of being expected to produce something every day of immediate market value or application.

The existence of the necessary organization and facilities for systematic investigation is one of the outstanding advantages which the agricultural industry enjoys; and the opportunity for their exercise with enlarged freedom is increasing far more rapidly than could have been anticipated. Education is of course largely responsible for this broadened view—the kind of instruction that comes not only through the colleges and the schools, but through the intimate contact of the county agent, the agricultural press and popular literature which now find as interesting features in agricultural progress as in other human subjects.

The effect of these things upon the public mind and upon the industry of farming is very pronounced. Already the latter is being recognized as an industry in which intelligence based on wide knowl-

edge is quite as essential as muscle and brawn.

A recent writer calls attention to the remark of Prof. Joseph Le Conte, made long ago, that each of the great professions first attained high standing when it was taught as such in universities. The professional men turned out under such teaching are no longer quacks but have a real command of the fundamental principles in their chosen field. Any profession has standing in so far as its fundamental principles have been developed and applied. To retain standing a profession must be continuously increasing its stock of knowledge of fundamental principles through research.

How applicable this is to agriculture—to the industry of farming and all that goes with it—will be fully apparent from its very modern history. A more striking illustration of change and development on the basis of knowledge and understanding could hardly be found; and the real significance of it is rapidly dawning, even though we are as yet little more than at the beginning. More and more the need is now understood for "the constant flow of new knowledge derived from the everlasting questioning of nature by trained men, whose eagerness is for the answer and the truth regardless of the immediate commercial value of that truth and answer." If the aim is right the practical value will follow surely enough and the result may be given deeper importance.

To insure this flow of knowledge which will give deeper insight and to maintain the standards which will mean steady advancement, there is still need for more men for research in agriculture—for men who know the aspect and significance of research and understand its methods and possibilities. This need results both from the growth in opportunity and the advance in grade of our agricultural inquiry. It is evidenced by the difficulty experienced by this Department and

the experiment stations in finding properly qualified people for their work.

If there is to be steady progress, advanced workers need to be produced at a faster rate than formerly. More of the suitable minds and temperaments need to be drawn into it. The provision of research scholarships and graduate fellowships has done considerable to direct men to this field and to afford opportunity for them to acquire the essential broad and rigid training. Such men as are now largely required can not be prepared over night, and hence the plans must be laid with foresight.

"We must welcome the inventive wonder but not wait for him to happen." The vast majority of that class are handicapped by lack of opportunity for learning the foundations of the sciences they are attempting to short circuit. Their spirit of research and patience in application to an idea are worthy of the investigator, but their deficiency lies in the fundamental knowledge which would avoid futile efforts and usually make their work better rewarded. The things that can be discovered by chance or even by earnest but insufficiently trained and informed effort have in very large measure been found out. The surface has been well skimmed. This was properly the first step, but it is now necessary to dig deep for the new knowledge.

The potential research worker is not an essentially distinct type, although he may possess certain qualities requisite to success. Contrary to the usual saying, he is probably less born than made. An eminent biologist has ventured the assertion that about two-fifths of the greatness of a man is born in him and three-fifths made. This leaves much for his environment and education.

In commenting on this subject, Dr. P. G. Nutting has made some interesting remarks as reported in a recent address. "Some writers," he says, "have spoken of the investigator as a rare individual, to be sifted out from educational institutions with great care for a particular line of work. My personal opinion is that a large percentage of the men students are fitted for research work if properly started along the right line. The investigator should have a mind at once fertile and well trained. His mind should be teeming with new ideas, but he should possess unerring judgment to reject those which are not logical or promising. . . . Fertility of mind is not so much an inborn quality of the mind itself as of the training and association which that mind has had."

He defines the best preparation for the investigator to be "a thorough grounding in the fundamental principles of his science—physics, chemistry, or whatever it may be. If he has this thorough knowledge of fundamental principles it is safe to say that in any properly organized research laboratory, with the proper leadership and companions, such a student will have many times as many useful

ideas as he can himself possibly follow up with research. Hardly any one who has completed advanced work in a science can read, say an abstract journal, without thinking of many problems which he would like to investigate."

The leaders of research "have not only a taste for research and logical minds to analyze clearly and attack problems with thorough scientific knowledge, but have a knowledge of the principles of research, getting the most out of their own minds, avoiding side issues, cooperating with their colleagues, and putting their most valuable results in permanent, readily available form. Research is one of the youngest of the professions and one with a promising future, but let no one enter it without thorough knowledge or a full understanding of its aims and methods."

And again he says, in speaking of the incentive to do the best that is in a man—to live up to his possibilities: "A great many students enter research because their favorite professors have made reputations in research or because their friends and colleagues are doing such work. Incentive by contact covers the psychology of getting started at the line of work you wish to become interested in. It is well known that the work itself produces a reaction on one's mind which makes it much easier to continue the work. . . . Incentive by contract to put forth our best efforts comes from putting ourselves under obligation to produce certain results," that is, the setting or acceptance of a task and undertaking to accomplish it.

This "incentive by contract," it may be noted, finds familiar illustration in station research in the project system so largely employed, and is one of the important advantages of it. The project outline is an attempt to block out on paper a definite line of inquiry, to answer a specific question or add a step toward the solution of a problem. Having formulated this undertaking and set his hand and mind to it, there is larger obligation and incentive for the investigator to accomplish the purpose as far as possible. It has become a venture on which his scientific reputation and ability may be gaged. This and the desire for accomplishment should be an incitement to hold to the main issue, refusing to follow side lines which develop; and it is also an added argument for the analysis of broad problems and the framing of projects within reasonable scope, so that the end may be promising of attainment.

Too broad and comprehensive projects reflect laudable ambition but point to inadequate realization of practicability and usual limitations. The large things often seem more attractive and worth while to the worker of limited experience and outlook, but to be practicable of attainment and bring credit to the investigator the project of definiteness and limited scope has proved to be far more promising in agriculture. Some large projects which have been under way ever since the Adams fund came are still very far from solution and are seen to be more intricate and less feasible in their entirety as knowledge advances. To abandon them is looked upon as an admission of weakness or of bad judgment, and so they may be continued after their defects have become apparent.

This is no argument against the project system but it is a sign for caution, which happily is finding expression in the newer undertakings.

The establishment and successful maintenance of a considerable number of technical agricultural journals in this country is a development of the past decade of much importance to agricultural research. It reflects in a striking manner the growth of agricultural investigation and the substantial support now available for periodical literature of this sort. It has increased materially the channels open for the publication of agricultural research, assembled many of the most important studies in the various specialized fields, and in other ways done much to unite workers and foster their interests.

The advantages of an American periodical devoted to agricultural science were foreseen by a number of teachers and investigators at a comparatively early date. In 1884 a meeting was held at the U. S. Department of Agriculture for the express purpose of considering the establishment of a journal of scientific agriculture. It was announced at this meeting that about forty of the leading agricultural workers of the period, among them Brewer, Johnson, Atwater, and Hilgard, had agreed to become contributors and that a guarantee fund had been secured to provide the necessary financial support, but the project was abandoned for the time being because of failure to secure an editor.

Advocacy of a journal continued, however, and in January, 1887, appeared the initial number of a monthly known as Agricultural Science. This was a private enterprise with Prof. Charles S. Plumb, then of the New York State Station, as editor and publisher. It constituted the first journal to be devoted to agricultural science not only in this country but in the English language. It also antedated by several weeks the passage of the Hatch Act, and by two years the establishment of Experiment Station Record.

The purposes of the new publication were set forth in its editorial columns as follows: "To publish original work, the results of experiments conducted in the promotion of agricultural science in America, either by individuals or otherwise; to disseminate knowledge relating to agricultural research, as obtained from researches carried on in Europe or other portions of the globe, that students and investigators may have the opportunity to learn of the work and results of co-laborers in the field; that students of agriculture,

in all its branches, may have a medium through which a free interchange of ideas may be brought about; that the field of agricultural research, so rapidly developing in America, may have a journal that will serve as a chronicler of work past, present, and to come, so as to form a valuable record of progress in agriculture; that agricultural science may be represented in one journal having no commercial or selfish motives, whose only effort shall be to uphold and promote investigation and research, and raise the standard of the field and its workers."

The publication of Agricultural Science continued with some vicissitudes and changes for eight years. In 1892 the management was assumed by Dr. Wm. Frear of the Pennsylvania State College with a corps of associates from various agricultural colleges, this Department, and elsewhere, and in 1894 it became the organ of the Society for the Promotion of Agricultural Science. Its final issue, that of December, 1894, appeared in June of the following year.

During its existence a considerable amount of experimental work was reported in its columns. Much space was also given to abstracts of agricultural literature, although this feature was less extensively developed than in the *Record*. The journal also contained reports of scientific meetings and other news notes of interest, and afforded opportunity for the discussion of current questions.

In spite of the unique position thus occupied by Agricultural Science, it appears that among the principal difficulties encountered in its publication was a lack of suitable material. This situation had indeed been predicted by Science, which in a review of the new journal expressed the opinion that one of the greatest handicaps would prove to be "a paucity of original investigations." Although a considerable body of research was steadily developing, this prophecy came true in so far as the material it was desired to publish outside the station and Department series was concerned, and there was also difficulty in obtaining the necessary financial support.

Following the suspension of Agricultural Science, station workers found themselves for many years restricted in the publication of their technical work to the regular bulletin series and the journals of general science. Much material was also sent abroad, many papers even appearing in German periodicals, notably Centralblatt für Bakteriologie, Parasitenkunde, und Infektionskrankheiten. With the advent of the Journal of Agricultural Science in England, in 1905, numerous American contributions were submitted to that periodical, but owing to a congestion of material and the limited number of issues, long delays of publication were entailed.

In 1908 the first of the American journals to be devoted to a single division of agricultural science began publication. This was

the Journal of Economic Entomology, issued bi-monthly and now completing its tenth volume. This journal was first financed through a stock company composed of members of the Association of Economic Entomologists, but in a few years was taken over completely by that association. The Journal of Home Economics was established by the American Home Economics Association in 1909, the American Breeders' Magazine, subsequently the Journal of Heredity, by the American Breeders' Association in 1910, and Phytopathology by the American Phytopathological Society in 1911. Of more recent date may be mentioned the Journal of the Society of Agronomy, which in 1913 replaced the Annual Proceedings of the American Society of Agronomy, the Journal of the American Association of Poultry Instructors starting in 1914, the Journal of the Association of Official Agricultural Chemists beginning in 1915, Soil Science founded by Rutgers College in 1916, and the Journal of Dairy Science published by the American Society of Dairy Science beginning with the current year.

Nearly all of these journals, it will be noted, are under the management of a corresponding society. In addition to providing for the publication of an increasing amount of original research, they afford a convenient medium for the printing of the societies' proceedings and otherwise serve to keep members in closer touch with matters of interest and promote the welfare of their respective divisions of science.

The establishment of the Journal of Agricultural Research by the U. S. Department of Agriculture in 1913, followed by the opening of its columns to contributions from the stations in 1914 under a cooperative arrangement with the Association of American Agricultural Colleges and Experiment Stations, should also be referred to. Unlike the topical journals, this publication is, of course, not restricted to a single phase of agricultural science. The large and steadily increasing number of contributions available for its use is evidenced in part by the change, two years ago, from monthly to weekly issues, attesting the amount and high grade of research now at hand from agricultural institutions in this country.

Meanwhile the stations have, of course, presented the results of much of their technical work in bulletin form, both in the regular series and in technical series, and workers have continued to employ the journals of general science, such as the Journal of the American Chemical Society, the Journal of Biological Chemistry, the Journal of Bacteriology, and the numerous botanical journals. Likewise workers in this Department have in recent years availed themselves quite largely of the privilege of utilizing non-Departmental publi-

cations. The last two volumes of the Record, corresponding to a year's work, contain titles of over five hundred such contributions.

The fact that these various channels of publication are now available is obviously of much advantage. It permits of a selection of the medium most suitable for a given purpose, and it relieves the congestion so rapidly replacing the scarcity of material complained of in the earlier days. It is, therefore, a matter of congratulation that the topical journals of agricultural science, which are rendering so useful a service, should have apparently passed the experimental stage and have established themselves among the recognized agencies for the dissemination of results of agricultural research.

# RECENT WORK IN AGRICUTURAL SCIENCE.

### AGRICULTURAL CHEMISTRY-AGROTECHNY.

Annual reports on the progress of chemistry for 1916, edited by J. C. CAIN, A. J. GREENAWAY, and C. SMITH (Ann. Rpts. Prog. Chem. [London], 13 (1916), pp. VIII+284).—This report corresponds to those of previous years (E. S. R., 35, p. 201).

Pervaporation, perstillation, and percrystallization, P. A. Kober (Jour. Amer. Chem. Soc., 39 (1917), No. 5, pp. 944-948, figs. 5).—Experiments are described in which collodion bags or containers are used for the procedures of evaporation, distillation, and crystallization. "Collodion and parchment membrane containers permit water to evaporate through the walls as though no membrane were present. This phenomenon is called pervaporation. Distillation by means of pervaporation is called perstillation, and can be conducted at ordinary atmospheric pressure with low temperatures as well as with vacuum. When a dialyzable constituent of a liquid within these containers reaches saturation, crystallization usually takes place on the outside. This phenomenon is called percrystallization."

The theory of the phenomena is briefly discussed.

On the quinone-phenolate theory of indicators: The electrical conductivity of solutions of phenolsulphonphthalein and of its bromo and nitro derivatives, E. C. White and S. F. Acree (Jour. Amer. Chem. Soc., 39 (1917), No. 4, pp. 648-652).

Reducing matter extractable from filter paper, R. S. McBride and J. A. Scherre (Jour. Amer. Chem. Soc., 39 (1917), No. 5, pp. 928-933).—In the study reported the authors conclude that some substance is extracted from the filter papers ordinarily used which reduces permanganate. It is indicated as being furfural or a closely related substance produced by oxidation and hydrolysis of the cellulose. Washing the filter paper previous to use is indicated as a great aid in avoiding excessive consumption of permanganate. Titration, however, even in the presence of the paper is not considered objectionable.

The preparation of hydrochloroplatinic acid by means of hydrogen peroxid, P. Rudnick and R. D. Cooke (Jour. Amer. Chem. Soc., 39 (1917), No. 4, pp. 633-635).—The following procedure is described:

Ten gm. of dried (but not ignited) platinum black is covered with 50 cc. of concentrated hydrochloric acid warmed to about 50 or 60° C. and 3 per cent hydrogen peroxid slowly added. Just enough hydrogen peroxid is kept present to maintain a moderate evolution of chlorin, which originates entirely on the platinum. When the platinum has been entirely dissolved the solution is evaporated to a volume of 100 cc. and is then ready for use. The use of dilute peroxid may cause the volume to become too great, in which case it is necessary to evaporate to a smaller bulk before all the platinum has been dissolved. Hydrogen peroxid of from 20 to 30 per cent strength has been found satisfactory in keeping down the volume of the solution.

Earlier references to the use of hydrogen peroxid as an oxidizer and the mode of the reaction are noted and briefly discussed.

The arsenates of lead.—III, Basic arsenates, C. C. McDonnell and C. M. SMITH (Jour. Amer. Chem. Soc., 39 (1917), No. 5, pp. 937-943).—Continuing previous work (E. S. R., 36, p. 501) the authors describe the preparation and properties of a number of basic arsenates of lead.

Indirect measurements of the rotatory powers of some alpha and beta forms of the sugars by means of solubility experiments, C. S. Hudson and E. Yanovsky (Jour. Amer. Chem. Soc., 39 (1917), No. 5, pp. 1013-1038).

The preparation of beta glucose, A. W. MANGAM and S. F. ACREE (Jour. Amer. Chem. Soc., 39 (1917), No. 5, pp. 965-968).

The preparation of xylose, C. S. Hudson and T. S. Harding (Jour. Amer. Chem. Soc., 39 (1917), No. 5, pp. 1038-1040).—A procedure for preparing xylose from cottonseed hulls is described. The yield obtained varies from 8 to 12 per cent, and the first lot of crystals obtained are almost colorless and pure.

On the cleavage in starch grains, A. Reuss (Ztschr. Untersuch. Nahr. w. Genussmtl., 32 (1916), No. 6, pp. 269, 270, figs. 6).—In the examination of a sample of bouillon cubes, starch grains were observed which exhibited peculiar cleavage. The cubes contained 50 per cent sodium chlorid. A preliminary study of the effect of various solutions on the cleavage of different kinds of starch grains was made, and the results are briefly noted.

The determination of gelatinization temperatures of starches by means of an electrically heated chamber on the microscope stage, A. W. Dox and G. W. Roark, Jr. (Jour. Amer. Chem. Soc., 39 (1917), No. 4, pp. 742-745).—The authors, at the Iowa Experiment Station, describe an apparatus similar to that previously noted by Francis and Smith (E. S. R., 35, p. 108). In the modified apparatus the chamber containing the slide is electrically heated. The manipulation of the apparatus and the procedure for determining the gelatinization temperature are described in detail.

The gelatinization temperature of starches of 13 different varieties of corn are submitted in tabular form.

Inflammability of carbonaceous dusts in atmospheres of low oxygen content, H. H. Brown and J. K. Clement (Jour. Indus. and Engin. Chem., 9 (1917), No. 4, pp. 347-349, fig. 1).—Continuing previous work (E. S. R., 37, p. 109) it has been shown that an inert gas mixture containing 12 per cent or less of oxygen would prevent a dust explosion from starting or propagating.

Hydrolysis of the soluble protein of Swede turnips, G. Williams (Jour. Agr. Sci. [England], 8 (1917), No. 2, pp. 182-215).—The following percentage composition of the protein obtained from the juice of Swede turnips (rutabagas) by heating to 90° C. for one-half hour is reported: Glycin, 0.27; alanin, 3.58; valin, 9.95; leucin and isoleucin, 9.01; phenylalanin, 4.47; tyrosin, 2.92; cystin, present; prolin, 4.17; aspartic acid, 6.98; glutaminic acid, 3.18; tryptophan, present; arginin, 3.12; histidin, 3.04; lysin, 4.35; ammonia, 1.21; humin bodies, 4.74; total, 60.99. One preparation of the protein prepared contained 14.09 per cent of nitrogen, 1.81 per cent of water, and 8.6 per cent of ash.

The procedures of Kossel and Kutscher, the ester method, and methods for isolating individual amino acids were used. The procedures are described in detail and the analytical data obtained discussed.

Experimental investigations of the plum (Prunus domestica).—II, Composition of plum seed oil, D. Feruglio and G. B. Bernardis (R. Lab. Chim. Agr. Udine Ric. Sper. e Attiv. Spiegata, 4 (1911-1914), pp. 111-118).—Experimental data relative to the physical and chemical constants and color reactions of the oil obtained by ether extraction of the finely ground material and qualitative tests of the fatty acids of the oil are submitted.

The oil is deemed to consist largely of the glycerid of oleic acid, together with smaller amounts of the glycerids of linoleic and palmitic acids. A small amount of an unidentified phytosterol was also present in the oil.

Tobacco seed oil, N. H. Cohen (Proefstat. Vorstenland. Tabak [Dutch East Indies], Meded. 14 (1915), pp. 57-65).—Some data relative to the yield of oil from the seeds of various crops of tobacco and the fertilizing value of the press cake are submitted and discussed, together with notes on the possible economic importance of the industry.

A sample of seed yielded on analysis the following percentage composition:  $P_2O_4$ , 1.5;  $K_2O$ , 2.06; nitrogen, 4.21; and oil, 14.38

The oleoresin of Douglas fir, A. W. Schorger (Jour. Amer. Chem. Soc., 39 (1917), No. 5, pp. 1040-1044).—The oleoresin in the heartwood of Douglas fir (Pseudotsuga taxifolia) was found to contain a volatile oil consisting largely of l- $\alpha$ -pinene, with small amounts of l-limonene and l-terpineol. The oil from the oleoresin obtained from the sapwood contained l- $\alpha$ -pinene, l- $\beta$ -pinene, and probably l-limonene. The "firpene" previously described as a new terpene is indicated as being highly active l- $\alpha$ -pinene.

The oxidase of Rhus diversiloba, J. B. McNair (Jour. Infect. Diseases, 20 (1917), No. 5, pp. 485-498, figs. 4).—The results of the investigation show that the darkening of the sap of R. diversiloba is due to oxidation and that the oxidation results in the total loss of the irritating poisonous properties of the sap. The oxidase found accelerated the transfer of molecular oxygen to phenols and aromatic amins. The oxidizing power is accelerated by dilute alkalis and retarded by dilute acids, and when boiled for a short time in aqueous solution is destroyed. The similarity of the oxidase to others previously isolated is noted.

In the study of the oxidase the author applied the Van Slyke apparatus (E. S. R., 31, p. 610).

Achroodextrinase, J. Effront (Compt. Rend. Acad. Sci. [Paris], 164 (1917), No. 10, pp. 415, 416).—The preparation of a dextrinase which rapidly converts into achroodextrin, amylodextrin, and erythrodextrin from Bacillus mesentericus found in various seed press cakes, distillery malt, and similar amylaceous material is noted. The enzym is precipitated by alcohol and ammonium sulphate at an optimum temperature of 40° C. It acts best in a medium neutral to methyl orange but is also active in slightly alkaline solution. Its action is retarded, however, by even very low acid concentration.

The use of the bacterial diastase in the textile industry, in converting starch residues into dextrin sirup, etc., is indicated.

The chemical nature of the vitamins.—III, The structure of the curative modifications of the hydroxypyridins, R. R. Williams (Jour. Biol. Chem., 29 (1917), No. 3, pp. 495-520, pl. 1).—Continuing the study previously noted (E. S. R., 36, p. 314) it has been found that the two crystalline forms of a-hydroxypyridin are isomeric and mutually convertible. The needle form alone is curative for polyneuritis. The corresponding crystal form of  $\beta$ -hydroxypyridin and the anhydrous forms of methylpyridone, trigonellin, and betain produced similar curative effects on polyneuritic birds. The last three, however, yielded negative results when tested for protective properties.

It is concluded that "the curative form of  $\alpha$ -hydroxypyridin is a pseudo betain, and that a feature conforming more or less closely in structure or energy conditions to the type of a betain ring is probably an essential characteristic of antineuritic vitamins." The theoretical possibility of the existence of such a structure in most of the simpler nitrogenous constituents of animal tissues, but especially in the nuclein bases, is pointed out.

Preliminary experiments are noted which indicate that "nicotinic acid may exist in a betain form and that the curative properties of Funk's vitamin fractions of yeast and rice polishings may have been due in part to this isomeric form of nicotinic acid or a polymer or simple derivative of it."

Titration of magnesium, F. W. BRUCKMILLER (Jour. Amer. Chem. Soc., 39 (1917), No. 4, pp. 610-615).—From experimental results obtained in the titration of magnesium as applied to water analysis the author indicates that magnesium can be determined volumetrically, provided great care is exercised in the formation of the phosphate precipitate in the one procedure, and special precautions taken in the titration of the iodin liberated by the arsenate precipitate from potassium iodid or the arsenious acid remaining after all the iodin has been expelled in the other procedure.

The modified methods are described in detail. Experimental data submitted indicate the accuracy of the methods as compared to the gravimetric procedure.

A study of the volumetric or Pemberton method for determining phosphoric acid, with some experiments showing the influence of temperature and the sulphuric acid radical on results, P. McG. Shuey (Jour. Indus. and Engin. Chem., 9 (1917), No. 4, pp. 367-370).—The author discusses the method and points out certain precautions necessary in the use of the procedure. Some experimental data relative to the temperature of titration are also submitted and discussed.

It is concluded in general that, "with a knowledge of the method and with strict attention to detail, very accurate and reliable results may be obtained. The fact that it is extremely delicate is a point in its favor."

The iodometric determination of ammonium sulphate, W. S. J. Schouten-Ilcken and R. W. Tuinzing (Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefstat. [Netherlands], No. 20 (1917), pp. 12-20).—The authors briefly review the distillation and other procedures used for the determination of ammonia in ammonium sulphate and other fertilizers. A procedure which depends on the following reactions is described:

- (1)  $2NH_2+3NaOBr=3NaBr+3H_2O+N_2$
- (2)  $(NH_4)_2SO_4+3NaOBr+2NaOH=Na_2SO_4+3NaBr+5H_2O+N_2$
- (3) NaOBr+2HI=NaBr+H<sub>2</sub>O+I<sub>2</sub>
- (4)  $2Na_2S_2O_3+I_2=Na_2S_4O_6+2NaI$

The alkaline-bromin solution is prepared by adding, with constant stirring, 15.5 gm. of bromin to 5 liters of sodium hydroxid solution (containing 15.5 gm. of NaOH). This solution is allowed to stand for several days and its titer then determined with a standard thiosulphate solution. Since the titer does not remain constant it should be determined every few days.

The ammonia determination is made by treating 10 cc. of a solution of ammonium sulphate (0.5 gm. in 100 cc. water) or a solution of ammonium superphosphate (1 gm. in 100 cc. of water) in a 700-cc. flask with 75 cc. of the alkaline-bromin solution. After having been set aside for several minutes 5 cc. of a 10 per cent solution of potassium iodid, 20 cc. of a 10 per cent hydrochloric acid solution, 5 cc. of a saturated solution of sodium carbonate, drop by drop, and 200 cc. of water are added to the mixture, in the order named. The liberated iodin is titrated with standard thiosulphate solution, using methylene blue as an indicator. From the amount of alkaline-bromin solution used the amount of nitrogen and ammonium sulphate present in the sample is calculated.

Analytical data submitted indicate the accuracy of the procedure. The method is recommended as being more economical than the usual distillation procedure in point of time and materials.

The determination of nitrogen in the form of calcium cyanamid in lime nitrogen, A. D. Berkhout, R. D. Hendriksz, and J. Wind (Verslay, Landbouwk, Onderzoek, Rijkslandbouwprocfstat, [Netherlands], No. 20 (1917), pp. 43-52).— The following method has been found to yield most reliable results:

Two gm. of the finely pulverized sample is rubbed up with repeated small amounts of distilled water and transferred to a 1,000-cc. measuring flask by decantation, using about 900 cc. of water. The flask is then placed in the shaking machine and thoroughly shaken for about one hour. The solution, after being made up to volume, is thoroughly shaken, and treated by either of the following methods:

- (1) Fifty or 100 cc. of the solution is neutralized in a flask with 10 per cent nitric acid and then treated with from 2.5 to 5 cc. of 2.5 per cent ammonia. Tenth-normal silver nitrate solution is immediately added in excess from a burette while the solution is being thoroughly shaken to precipitate the cyanamid as silver cyanamid. The material in the flask is made up to volume and after thorough agitation is filtered. After this precipitation the solution should be decidedly alkaline. From 50 to 100 cc. of the filtrate, after being acidified with from 5 to 10 cc. of 10 per cent nitric acid, is titrated with tenth-normal ammonium thiocyanate solution, using from 2.5 to 5 cc. of a cold saturated ferric ammonium alum solution as indicator. If chlorids are present they should be previously determined and the proper correction made.
- (2) One hundred cc. of the solution is transferred to a 250-cc. beaker, neutralized with 10 per cent nitric acid, and after the addition of 2 cc. of 10 per cent ammonia a slight excess of tenth-normal silver nitrate is added with thorough agitation. The precipitated silver salt is quantitatively filtered, thoroughly washed, and the wet filter and contents subjected to a Kjeldahl nitro gen determination, using 10 cc. of 50 per cent sulphuric acid, 0.6 gm. of mer cury, and 20 cc. of a mixture of 1 liter of sulphuric acid (specific gravity 1.84) and 200 gm. phosphorus pentoxid.

On the Duclaux method for the estimation of the volatile fatty acids, F. W. Upson, H. M. Plum, and J. E. Schott (Jour. Amer. Chem. Soc., 39 (1917), No. 4, pp. 731-742).—From the results of a critical study the authors conclude that small, unavoidable variations in the experimental results such as are within the limits of error of the method may cause such wide variation in the calculated results as to make them of no quantitative value. When more than two acids are present in a mixture practically identical series may be calculated from mixtures of different acids in varying proportions. "Results which indicate the presence of one acid may just as well be calculated in terms of three or more acids. Small amounts of acids may be distributed just as well between the acids next higher and lower in the series."

The theory of the method is deemed to be unsound, and the procedure therefore not to be applicable for either quantitative or qualitative determinations of the composition of unknown mixtures of fatty acids.

The experimental data are submitted and discussed in detail.

A note on the Duclaux method for volatile fatty acids, A. R. Lamb (Jour. Amer. Chem. Soc., 39 (1917), No. 4, pp. 746, 747).—From a critical study of the method in connection with some investigations on the fermentation of corn silage the author, at the Iowa Experiment Station, considers it to be impracticable to attempt to determine more than two or three acids in the same fraction. "By proper fractional distillation the acids in the mixture may be quite well separated. This obviates the necessity of calculating as many as four acids from a single distillation, which is objected to by Upson et al." (as noted above).

The lack of agreement between different sets of Duclaux's constants is considered to be due to impurities in the acids used and to avoidable experimental

variations, rather than to unavoidable experimental variations claimed above. The author considers that "it is possible under proper conditions to obtain much more accurate results with the method than have generally been obtained."

The Duclaux method, F. W. J. BOEKHOUT and J. J. O. DE VBIES (Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefstat. [Netherlands], No. 20 (1917), pp. 79-90).—In a critical study of the Duclaux method the authors have determined constants practically the same as those obtained by the originator of the method. Results obtained from a mixture of more than two acids arconsidered not to be trustworthy.

The theory and use of the procedure are discussed in some detail, and analytical data submitted in tabular form.

The systematic extraction of aqueous solutions with ether, J. Pinnow (Ztschr. Untersuch. Nahr. u. Genussmtl., 32 (1916), No. 6, pp. 257-268).—Physical-chemical data relative to extraction with varying volumes of the solution, concentration of the solution, time, etc., of citric, succinic, and lactic acids, pyrogallol, and caffein are submitted and discussed.

The determination of added water in ground meats and sausages, C. BAUMANN and J. GROSSFELD (Ztschr. Untersuch. Nahr. u. Genussmtl., 32 (1916), No. 11, pp. 489-493).—The use of the ratio total water: nitrogen is considered to be easier and more reliable than that of the others commonly used for the determination of added water. For fresh meats this ratio (average) has been found to be 18.3. The following formula is proposed for calculating results:

Added water=Total water-(nitrogen×18.3).

Some analytical data are submitted.

The alkalinity of cocoa, ARPIN (Ann. Falsif., 10 (1917), No. 99-100, pp. 10-14).—Analytical data of a number of samples of cocoas with especial reference to the alkalinity of the ash are submitted and discussed.

The determination of the alkalinity of cocoa, X. Rocques (Ann. Falsif., 10 (1917), No. 99-100, pp. 14-17, fig. 1).—Modified procedures of the official French method for the determination of total ash, water-soluble and insoluble ash, alkalinity of the soluble ash, and the phosphoric acid in the soluble ash are described and discussed.

Moisture determination in spices and similar products, A. Scholl and R. Strohecker (Ztschr. Untersuch. Nahr. u. Genussmtl., 32 (1916), No. 11, pp. 493-499).—This is a general discussion of the subject, together with some experimental data obtained in a study of methods commonly used for moisture determinations.

It is concluded that in general the distillation procedure for the determination of moisture is applicable to spices, and that comparatively accurate results are obtainable. The procedure is especially suited to samples which contain large amounts of volatile matter. It could not well be applied, however, to samples which contain inorganic salts with water of crystallization without some modification.

The determination of ammonia in wine and its significance, W. J. BARAGIOLA and C. Godet (Ztschr. Untersuch. Nahr. u. Genussmil., 30 (1915), No. 5, pp. 169-216. fig. 1).—The literature on the determination of ammonia in wine and other biochemical studies is reviewed and the results of an original investigation on the subject submitted.

The distillation with magnesium oxid in vacuo is deemed to be accurate and satisfactory for all practical and control determinations since the amount of amins or other bases is ordinarily only very small. For very exact work where

it is desired to separate the ammonia from the amins and other bases the precipitation of ammonia as ammonium-magnesium phosphate is recommended.

The procedures which are applicable to fermented and unfermented fruit wines and juices, together with analytical data relative to the effect of other substances present on the determination of ammonia, are described in detail.

The amount of ammonia in wines was found to vary from nothing to 150 mg. per liter. The French limit of 20 mg. per liter for maximum content is considered to be unsatisfactory. Fruit wines appear to be very poor in ammonia.

The significance of the determination of ammonia for both practical and scientific purposes is indicated.

The determination of ammonia in wine, W. J. BARAGIOLA and O. SCHUPPLI (Ztschr. Untersuch. Nahr. u. Genussmtl., 32 (1916), No. 10, pp. 441-444).—Supplementary to the study noted above the distillation with magnesium oxid is again strongly recommended. The use of the precipitation procedure is advised only in cases where it is desired to determine small amounts of volatile amins and other bases that might be present.

The precipitation of ammonia was found not to be complete except in an excess of sodium phosphate. The use of 12 gm. of sodium phosphate rather than 5 gm. as in the previous procedure is recommended.

A method for the examination of methyl salicylate, A. R. Albright (Jour. Amer. Chem. Soc., 39 (1917), No. 4, pp. 820-825).—A method for examining a methyl salicylate oil and other phenolic substances or impurities present which depends on the conversion of the substances into the same crystalline derivative (the benzoate) and the microscopical examination of the resulting crystals is described and discussed.

A study of certain ferments with a view to determining a method for the differentiation of pasteurized milk from raw milk .-- I, Reductases, R. E. LEE and M. G. MELLON (Jour. Indus. and Engin. Chem., 9 (1917), No. 4, pp. 360-367, figs. 7).—From the study reported the authors conclude that methylene blue, as it occurs in Schardinger's F. M. reagent (5 cc. of a saturated alcoholic solution of methylene blue, 5 cc. of 40 per cent formaldehyde, and 190 cc. of water), is not decolorized by normal milk in less than 20 minutes. In cases of decolorization effected in 10 minutes or less the milk was found to contain 1,000,000 or more microorganisms per cubic centimeter. teurized at 70° C. for 10 minutes, unless allowed to stand for 48 hours before testing (or until the bacterial content was largely increased), or old milk in which the preservative (formaldehyde) inhibited the growth of bacteria, also did not decolorize methylene blue. The reagent was ordinarily decolorized by normal milk which had stood under ordinary temperature conditions for from 24 to 48 hours. Pasteurization increased the time required for the decolorization of the reagent.

In general, no ratio was found to exist between the time required for decolorization and the number of bacteria in the milk. A general relation, however, appeared to exist between these two factors up to a given point of acidity. Because of a lack of parallelism between these two factors it is indicated that "reductase is of bacterial origin but that not all bacteria found in milk produce this enzym. . . . It seems probable that formaldehyde either gradually retards the action of the reductase or destroys it. This is a matter, however, for more careful investigation in the future."

The experimental data are submitted in tabular and graphical form,

Characteristic milk powder forms, C. GRIEBEL (Ztschr. Untersuch. Nahr. u. Genussmtl., 32 (1916), No. 10, pp. 445-447, figs. 2).—Some notes on the differ-

ences in the microscopic appearance of whole milk and skim milk powders are submitted.

A further contribution to the method for the determination of fat in cheese, N. A. Brodrick-Pittard (Ztschr. Untersuch. Nahr. u. Genussmil., 32 (1916), No. 8, pp. 354-358).—Data submitted show that the presence of greater or lesser amounts of lactic acid in cheese does not exercise an influence on the results in the determination of fat by extraction with ether. The difference in the acid content of fat obtained by extraction with petroleum ether and that extracted with ether is considered to be chiefly due to the insolubility of the oxy-fatty acids in petroleum ether.

From results previously obtained, together with those submitted, the extraction with ether is considered to be the preferable procedure.

The microscopic examination of colza and rape seed cake, J. A. EZENDAM (Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefstat. [Netherlands]. No. 20 (1917), pp. 1-11, pls. 5).—The preparation of samples for microscopic examination and the microscopic appearance of various species of Brassica are described. The value of microscopical examination in the control of feeding stuffs is indicated.

The chemical examination of rape seed press cake with reference to its deleterious effect as a feeding stuff, G. B. VAN KAMPEN (Verslag, Landbouwk, Onderzoek, Rijkslandbouwproefstat, [Netherlands], No. 20 (1917), pp. 53-70, fig. 1).—Previous work in regard to the determination of mustard oil in samples of rape seed cake is reviewed.

From the study reported it is concluded that when the odor test is used to determine whether or not the sample is harmful it should always be made with the addition of thymol or sodium fluorid. The determination of the amount of mustard oils and the nitrogen content of the thiosinamins is considered to be a more reliable procedure. The limiting figures for these substances reported by earlier workers are, however, not considered to be reliable.

The determination of the water-soluble carbohydrates is deemed to be very important in determining the freshness of the sample and thus indicating the probable harmfulness of the material as a feeding stuff.

Cider and the cider industry in England, G. WARCOLLIEB ET AL. (Bul. Mens. Off. Renseig. Agr. [Paris], 15 (1916), Jan.—July, pp. 167-199; Aug.—Sept., pp. 314-335).—This is a detailed report of the findings of the French commission appointed by the minister of agriculture to investigate the industry in England.

Washing fruits and vegetables, A. W. BITTING (Nat. Canners Assoc. Bul. 12 (1917), pp. 28, figs. 31).—This is a brief general discussion of the subject, together with a description of the various forms of apparatus which have been proposed and used in the canning industry.

Beet molasses: Its composition and utilization, S. J. Osborn (Metallurg. and Chem. Engin., 16 (1917), No. 8, pp. 436-443, figs. 3).—This is a general discussion of the subject under the topics of theories of molasses formation, commercial importance of molasses formation, melassigenic action of various nonsugars, composition of molasses, cane molasses, utilization of beet molasses, cattle feeding, alcohol production, molasses processes, recovery of potash, and miscellaneous processes.

Notes on the preparation, by the distillation and by the combustion of wood, of acid coagulants, and on their effect on the quality of rubber, B. J. EATON and G. S. WHITBY (Agr. Bul. Fed. Malay States, 5 (1917), No. 4, pp. 124-134).—Data relative to the use of crude pyroligneous acid, obtained from rubber wood and mangrove, and a "smoke solution" (obtained by passing smoke through water) as coagulants, together with vulcanization and strength tests, are reported.

Pyroligneous acid was found to retard the vulcanization somewhat, although the effect was not constant. The acid distilled from the mangrove had a more marked effect than that distilled from the rubber wood. The results are discussed in detail.

Notes on the rubber from Eucommia ulmoides, A. F. Sievers (Jour. Amer. Chem. Soc., 39 (1917), No. 4, pp. 725-731, fig. 1).—Extraction data of the elastic constituent of the bark of E. ulmoides, solubility of the ether-extracted caoutchouc in various solvents, percentage of elastic constituent extracted from the bark by various solvents and in various time periods under constant agitation, comparative effect of various solvents on caoutchouc from Eucommia as compared with genuine specimens of crude rubber, and relative rapidity of solvent action of various organic solvents on a Siam, a Ceylon, and a Eucommia specimen of rubber are submitted and discussed.

The artificial drying of tobacco, O. De Vries (Proefstat. Vorstenland. Tabak [Dutch East Indies], Meded. 10 [1914], pp. 1-13, figs. 3).—Experiments on the artificial drying of tobacco are described and discussed. The value of the control of ventilation, temperature, and humidity in artificial drying is indicated.

#### METEOROLOGY.

A new system of weather prediction, R. Paresce (Sci. Amer. Sup., 83 (1917), No. 2165, p. 403, figs. 4).—This is a brief review of a report by F. Vercelli on perodic oscillations and prediction of atmospheric pressure. It is claimed that these furnish a basis for predicting weather conditions months in advance.

Normal anomalies of the mean annual temperature variation, H. Arcrowski (Phil. Mag. and Jour. Sci., 6. ser., 33 (1917), No. 198, pp. 487-495, figs. 4).— It is stated that if in case of long series of observations the averages for each day of the year are taken into consideration instead of monthly means, curves representing the annual variations of atmospheric temperature show most remarkable anomalies. From a study of certain typical examples of such curves, the author reaches the conclusion "that in a comparative study of the anomalies of the annual temperature variation Teisserenc de Bort's conception of the great centers of action of atmospheric circulation will find an extensive application; because, although at present it would be premature to try to explain why it is that some changes of phase may occur simultaneously in the Arctic and Antarctic regions, or in North America and Siberia, it seems impossible to conceive such correlations without supposing some relationship with the exchange of pressure between the seasonal and permanent centers of action."

Effect of short period variations of solar radiation on the earth's atmosphere, H. H. Clayton (Smithsn. Misc. Collect., 68 (1917), No. 3, pp. 18, pls. 8, flgs. 3).—Using the Pearson method in correlating the bolometric measurements of variations in solar radiation as recorded by Abbott and his associates at the Mount Wilson observatory with atmospheric changes as observed at Pilar in central Argentina, the author concludes "(1) that there is an intimate relation between solar changes and meteorological changes of short period, and that measurements of solar radiation like those made by Dr. Abbott and his associates have the greatest importance for meteorology; (2) that there is a class of meteorological changes which have their origin in equatorial regions, and by a transference of air, probably in the upper layers, are felt within a few days in higher latitudes. These changes are the complement of the complex meteorological drift which goes from west to east in temperate latitudes with a component of motion from pole to equator in both hemispheres."

The influence of intense and prolonged cannonading on rainfall, H. Deslandres (Compt. Rend. Acad. Sci. [Paris], 164 (1917), No. 17, pp. 613-615; abs. in Rev. Sci. [Paris], 55 (1917), No. 9, p. 284).—It is stated that artillery discharges electrify and ionize the atmosphere to an extent which apparently influences rainfall, although to a much less extent than the great atmospheric currents and depressions. To reach a positive conclusion on this point, however, one must carefully consider all of the elements which enter into the phenomenon, particularly the degree of ionization of the air and the intensity and character of the electric field.

Commenting on the above, G. Lemoine expresses the opinion that if frequent and prolonged artillery discharges have any influence on rainfall it is only in connection with light rains.

Does violent cannonading induce rainfall? SEBERT (Compt. Rend. Acad. Sci. [Paris], 164 (1917), No. 18, pp. 663-669; abs. in Rev. Sci. [Paris], 55 (1917), No. 10, p. 317).—Referring to discussions of this subject by Deslandres and Lemoine, noted above, a question is raised as to whether intense cannonading does not create atmospheric disturbances which may induce heavy and prolonged rainfall. The author is of the opinion that the subject is of sufficient importance to warrant careful investigation in certain restricted areas by meteorological bureaus and agricultural experiment stations.

Investigation of the influence of climatic conditions on the composition of plant oils, G. V. Pigulevski (Zhur. Russ. Fiz. Khim. Obshch., 48 (1916), pp. 324-341; abs. in Jour. Chem. Soc. [London], 112 (1917), No. 653, I, p. 189).—
"Evidence is adduced showing that among plants belonging to one and the same subfamily the iodin number of the essential oil increases as the geographical distribution of the plant extends farther toward the north."

The past winter, C. Harding (Nature [London], 99 (1917), No. 2484, pp. 294, 295).—The characteristic features of the five months December, 1916, to April, 1917, which was an abnormally cold and wintry period generally over the British Islands, are briefly reviewed—Similar conditions prevailed over western and northern Europe.

### SOILS—FERTILIZERS.

Soil moisture and plant succession, G. D. Fuller (Trans. Ill. Acad. Sci., 7 (1914), pp. 68-73).—Data representing the range of soil moisture in the upper subterranean strata of the vegetation of various associations are reported.

"The rate of evaporation in the cottonwood dune association, both by its great amount and by its excessive variation, seems a quite sufficient cause for the xerophytic character of the vegetation and for the absence of undergrowth, in spite of the constant presence of growth water. The pine and oak dune association resemble one another closely in their supply of growth water. The former is slightly more xerophytic during the midsummer weeks. The amount of growth water in the various associations varies directly with the order of their occurrence in the succession, the pioneer being the most xerophytic. The ratios between the evaporation and growth water in the beech-maple forest, oak-hickory forest, oak dune, pine dune, and cottonwood dune associations have been shown to have comparative values of 100, 65, 20, 17, and 15, respectively, and the differences thus indicated are sufficient to be efficient factors in causing succession."

Eight references to literature bearing on the subject are appended.

Evaporation and soil moisture in forests and cultivated fields, J. F. Groves (Trans. Ill. Acad. Sci., 7 (1914), pp. 59-67, figs. 5).—Experiments on

a beech-maple forest soil and on the bordering cultivated fields of wheat and oats are reported.

It was found that "the evaporation rate at the surface of cultivated fields is somewhat parallel to that of the climax beech-maple forest and shows corresponding variations due to changes in weather conditions. After crops are harvested the evaporation rate is greatly increased, due to the increased exposure. In the beech-maple forest the soil moisture is much higher in the stratum, due largely to the great amount of humus. In this association the wilting coefficient was reached only once during the season. In the wheat field the upper stratum shows a marked response in soil moisture due to periodic rainfall. In this association the soil moisture falls decidedly below the wilting coefficient after the wheat is harvested. The upper stratum of the oat field also shows considerable variations which correspond more or less to those in the wheat field."

Three references to literature bearing on the subject are appended.

Tobacco soils and the tobaccos grown thereon, N. H. Cohen (Proefstat. Vorstenland. Tabak [Dutch East Indies], Meded. 11 (1914), pp. 18, pls. 3).—Analyses of 20 samples of tobacco soils from eight different localities in Java are reported and compared with analyses of the tobacco grown on these soils.

It was found that the solubility in citric acid of the phosphoric acid of the soils decreased as the soils were heavier and more weathered. The content of available lime of the different soils increased with the content of finest particles in the soil. The quotient of the content of lime soluble in 25 per cent hydrochloric acid and content of available lime decreased as the content of finest particles increased and approached unity. No relation was found between the content of potash in a soil and the tobacco grown thereon, and little relation was shown for phosphoric acid.

Heavy soils with a low content of citrate-soluble phosphoric acid bore tobacco with a lower phosphoric acid content than light soils. Parallel relations existed between the content of available lime in soil and the lime content of the corresponding tobacco. No relation was established between the chlorin and potash content of tobacco and its burning qualities. The whiteness of the ash of the tobacco increased with the lime content, but its relation with the magnesia content was doubtful.

Soil survey of Cowley County, Kansas, E. C. and R. H. Hall and B. W. Tillman (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 46, pls. 2, fig. 1, map 1).—This survey, made in cooperation with the Kansas Agricultural College and Experiment Station, deals with the soils of an area of 725,120 acres in southeastern Kansas, the surface of which is predominantly undulating or gently rolling. The county lies in the Great Plains region. The surface drainage is said to be generally good.

The upland soils of the county are of residual origin and the stream bottom lands of alluvial origin. Twenty-three soil types of nine series are mapped, of which the Summit silty clay loam, the Summit silt loam, Crawford silt loam, and Gerald silt loam cover 29.5, 13.2, 11, and 10.8 per cent of the area, respectively. Chemical analyses are included of some of these soils.

Report on Mecklenburg County soils, agriculture, and industries, C. B. WILLIAMS, W. E. HEARN, J. K. PLUMMER, and W. F. PATE (Bul. N. C. Dept. Agr., 38 (1917), No. 4, pp. 47, pl. 1, figs. 12).—This is No. 1 of the North Carolina soil reports. It supplements the survey made in cooperation with the Bureau of Soils of the U. S. Department of Agriculture (E. S. R., 29, p. 16), and includes average chemical analyses of the soil types of the county, together

with recommendations as to fertility requirements based on field experiments with the prevailing types.

"Experiments which have been conducted in this county on the Cecil clay, in Iredell on Cecil clay loam, and in Gaston on Cecil sandy loam have shown for several years that nitrogen and phosphoric acid are the constituents chiefly needed. Potash has not been generally shown to be essential except for such crops as tobacco and potatoes."

Lime requirements of some acid soils, S. D. Conner (Jour. Assoc. Off. Agr. Chem., 3 (1917), No. 1, pp. 139, 140).—Studies at the Indiana Experiment Stattion of the lime requirements of very acid peat, peat, peaty sand, loam well supplied with organic matter, and silt loam soils, using the Hopkins potassium-nitrate method, the Veitch limewater method, the Hutchinson-MacLennan calcium-bicarbonate method, and the Jones calcium-acetate method, are reported.

It was found that the Hopkins method gave much lower results than the others, especially on soils containing much organic matter. "This method possibly gives too low an estimate as an average; but . . . in most cases it is just as near as any other method to the amounts of lime which have given profitable returns by actual tests on the crops. While the Veitch method doubtless more accurately determines the amount of lime that a soil has the capacity to absorb, . . . it is not profitable to add this much lime to soils high in organic matter. The results of these tests indicate that organic acidity is much less toxic in soils than inorganic acidity. The Jones calcium-acetate method gives higher results than the calcium-bicarbonate method. . . None of the soilacidity methods can be used as an exact estimate of the most profitable amount of lime to be added to the soil."

In this connection the opinion is expressed that "a soil-acidity estimation is probably the most important single test that can be made in the laboratory to determine the chemical requirements of the soil."

Study of soil containing residual limestone, H. A. Noves (Jour. Assoc. Off. Agr. Chem., 3 (1917), No. 1, pp. 151-153).—Studies at the Indiana Experiment Station of the acidity of a residual silty clay orchard soil containing about 60 per cent of fine silt and 20 per cent of clay and underlaid with limestone rock are reported. Samples were taken representing the following depths: Surface to 9 in., 9 to 18 in., 18 to 27 in., 27 to 36 in., and 36 to 45 in. Acidity was determined by the Hopkins potassium-nitrate method.

It was found that the acidity did not decrease with the depth and showed no regular decrease or increase dependent upon the distance from bed rock. The acidity results could not be correlated with either the percentage of nitrogen or the volatile matter in the samples. The presence of limestone fragments in this acid soil leads to the conclusion that coarse screenings would not correct the acidity and that for acid silt and clay soils finely ground limestone is necessary.

The character of certain soils in the area devastated by the eruptions of the Soufrière of St. Vincent in 1902-3, H. A. Tempany (West Indian Bul., 16 (1917), No. 2, pp. 126-137, fig. 1).—Physical, chemical, and biological studies of samples from the ash deposits in the Carib country of St. Vincent which were laid down at the time of the eruption of the St. Vincent Soufrière in 1902 are reported. These deposits are said to range in thickness from 14 to 18 in.

"Physically the soils were found to consist of coarse sandy types; they showed shrinkages ranging between 1 and 2 per cent, thereby indicating the formation of a certain amount of colloidal material. Chemically the soils showed small contents of organic carbon and nitrogen; they were extremely

deficient in calcium carbonate; [and] they showed the presence of moderate amounts of available phosphoric acid and potash. Characteristically the soils all possessed an appreciable degree of acidity, as evidenced by the lime requirement for neutralization.

"The biological activity of the soils was found to be as follows: The value for the figure for partial sterilization indicated the existence of a moderate activity of putrefactive bacteria. Nitrogen-fixing organisms of the Azotobacter type were found to be present, and the soils showed small, but appreciable, nitrogen-fixing power. The soils also possessed appreciable ammonifying power, but were completely deficient in nitrifying power.

"During the 14 years which have intervened between the eruption and the date on which the samples were taken, considerable progress has been made in the conversion of the sterile ash deposits then laid down into fertile soil."

The "gall patches" in Antigua soils, H. A. Tempany (West Indian Bul. 16 (1917), No. 2, pp. 137-144, fig. 1).—Chemical and biological studies of so-called gall patches in sugar cane soils, together with cultural experiments with cane and examinations of cane, are reported.

"The results indicate clearly that the effect in question is due to the presence of sodium carbonate in the soil. The origin of this sodium carbonate is attributed to interaction between the calcium carbonate and the sodium chlorid dissolved in soil water and brought up from saliniferous deposits at deeper levels."

Sterilization and fatigue of soil (Sta. Agron. Finistère et Lab. Dept. Bul., 1914-15, pp. 24-36).—Experiments on the treatment of soil-growing turnips with benzin and toluene in amounts equivalent to 100, 125, 150, 175, and 200 liters per hectare showed that the largest yield of turnips by weight was obtained with benzin added at the rate of 100 liters per hectare (about 10.7 gal. per acre). The benzin was also superior to toluene in amounts of 125 liters per hectare. The toluene gave better results in the higher concentrations, but a treatment of 100 liters per hectare of benzin gave as good result as 175 liters of toluene.

Influence of crop, season, and water on the bacterial activities of the soil, J. E. Greaves, R. Stewart, and C. T. Hirst (U. S. Dept. Agr., Jour. Agr. Research, 9 (1917), No. 9, pp. 293-341, fig. 1).—The work of others bearing on the subject is briefly reviewed and investigations conducted at the Utah Experiment Station with a rich sedimentary soil are reported. Twenty  $\frac{1}{16}$ -acre plats were divided into five equal sets of plats. The first set was left fallow, the second was planted to alfalfa, the third to corn, the fourth to potatoes, and the fifth to oats. One of these sets received a maximum, one a medium, and one a minimum application of water, and one set was unirrigated. The plats were sampled during the spring (about the middle of April), midsummer (about the last of July), and in the fall (the last of October or the first of November). The samples were analyzed for moisture, nitric nitrogen, number of bacteria developing on synthetic media, and the ammonifying and nitrifying powers.

It was found that "the quantity of nitric nitrogen in the surface 6 ft. of alfalfa soil is comparatively low throughout the season, but is higher in the fall than in the spring or summer. The quantity present decreases as the water applied increases; yet the quantity formed in the soil increases as the water applied increases, but is greatest per acre-inch of water when only 15 in. of water are applied. The quantity of nitric nitrogen in the surface 6 ft. of potato, oats, corn, and fallow soil decreases as the water applied increases; but the quantity formed for each of the cropped soils is greatest where the largest quantity of water was applied. The quantity formed per acre-inch of water applied is greatest where only 15 in. of water were applied.

"Large quantities of nitric nitrogen disappeared from the fallow soil during the summer months. This is attributed to the growth of bacteria, which transforms it into protein substances and not to denitrification.

"The larger applications of irrigation, 37.5 and 25 in. of water, carry much of the nitric nitrogen beyond the sphere of action of the plant, and this accounts for the decrease in crop yield, which is often noted when excessive quantities of irrigation waters are applied to a soil. The application of water to a soil depresses the number of organisms which will develop upon synthetic agar in alfalfa, oats, and potato soil, but increases them in fallow. The results obtained with the corn are irregular. The ammonifying powers of all the soils, except the alfalfa, were increased by the application of irrigation water. Water increased the nitrifying powers of all the soils except the oats soil.

"There was a difference of 2° F. in the temperature of the soil of irrigated and unirrigated in favor of the unirrigated. This difference in temperature was perceptible to a depth of 4 ft. The number of organisms was higher in the cropped than in the fallow plats, and this is probably due to the plant residues left upon the cropped soil."

The soils in the order of increasing ammonifying powers were alfalfa, oats, corn, potato, and fallow soils. "By naming them in the order of increasing nitrifying powers, they are fallow, corn, oats, alfalfa, and potato [soils]. The alfalfa not only feeds closer upon the nitric nitrogen of the soil than do other crops but it also increases the nitrifying powers of the soil. Hence, it would deplete the soil of its nitrogen more rapidly where the entire crop is removed than would other crops.

"The use of irrigation water increases the bacterial activities of the soil which render soluble the nitrogen, and where excessive quantities of water are used considerable of this is washed from the soil, thus unnecessarily depleting the soil of its nitrogen. This in turn gives diminished yields on the soil."

The behavior of legume bacteria in acid and alkaline media, R. C. SALTER (*Proc. Iowa Acad. Sci.*, 23 (1916), pp. 309-313, figs. 2).—Experiments made to compare the effects of acid and alkali on legume bacteria are reported, in which it was found that "alfalfa bacteria are benefited by an alkaline reaction, while the clover bacteria do best in a neutral or slightly acid medium. The difference in behavior of alfalfa and red clover plants in acid soils is characterized by a corresponding difference in the behavior of their symbiotic bacteria."

Effect of decomposing organic matter on the solubility of certain inorganic constituents of the soil, C. A. Jensen (U. S. Dept. Agr., Jour. Agr. Research, 9 (1917), No. 8, pp. 253-268).—This paper "deals with the solvent action on certain inorganic soil constituents of the water-soluble decomposition products of manures and other organic fertilizers. Soils were extracted (1) with soluble organic matter obtained from decomposing green manures and from stable manures; (2) with soluble organic matter obtained from thoroughly decomposed green manures; (3) with artificially prepared humus solutions obtained by hydrolyzing organic substances with acids; and (4) with osmosed organic solutions derived from the decomposition of organic matter. In addition, stable and green manures were added directly to the soil and the effect of this treatment was noted (1) on the amounts of certain soil minerals dissolved out with water, and (2) on the change produced in the specific electrical conductivity of the soil. . . . Two types of soil, a clay loam and a sandy loam, were used.

"In the four soil extractions these organic solvents removed from the soil from two to five times as much calcium as was added to the soil with the solvents. In most cases these solvents removed more magnesium from the soil in the four extractions than was added with the solvents, the increase varying from a small fraction to about 80 per cent. The amount of iron and phosphoric

acid removed from the soil by these organic solvents in the four soil extractions did not equal the total amount added to the soil with the solvents. However, the amount of iron dissolved from the soil by the organic solvents exceeded the amount dissolved by distilled water from 1 to 5.5 times. The amount of phosphoric acid dissolved from the soil exceeded the amount dissolved by water from 1.7 to 5.4 times. These various organic solvents, whether derived from a leguminous or a nonleguminous crop, had about equal solvent action on the soil minerals

"Organic solvents obtained from cow manure treated in a manner similar to the freshly decomposing green manures did not dissolve as much calcium from the soil as the solvents derived from the latter substance. They exerted about the same solvent action, however, on the other elements under investigation. The solvent action of these organic extracts on the soil minerals appeared to be due both to the inorganic salts present in the organic solvents and to the organic compounds. Green manures kept moist until thoroughly decomposed gave organic solvents which removed calcium from the soil in amounts several times that added with the organic solvents. These solvents also removed magnesium, phosphoric acid, and iron considerably in excess of the amount dissolved by water alone. The organic solvents showed no alkaline reaction with phenolphthalein nor acid reaction with methyl orange. Three per cent of green manures and stable manure mixed with soil and allowed to undergo partial decomposition increased the solubility of calcium and phosphoric acid in the soils from 30 to 100 per cent.

"Artificial humus solutions free from calcium, magnesium, iron, and phosphoric acid were prepared by hydrolyzing green manures and sugar with strong acid, washing them free from acid, and extracting with ammonia. These organic solvents, when freed from ammonia, increased the solubility of calcium in the soil, compared with its solubility in water, by amounts varying from a few parts to 240 parts per million of soil. They also increased the solubility of magnesium, phosphoric acid, and iron, but to a less extent.

"In brief, the solubility of calcium, magnesium, iron, and phosphoric acid in citrus soils of the Riverside [Cal.] district is measurably increased by the addition of green manure, stable manure, or their extracts. This increase in solubility is due in part to the action of the inorganic salts contained in the organic substances or their extracts and in part to the solvent action of the soluble organic compounds formed during organic decomposition. The fact that a deficiency in soluble iron is known to induce certain types of chlorosis suggests that the beneficial effects following the addition of organic matter to citrus soils may have been in part due to its solvent action on iron and other soil compounds."

Conversion of soluble phosphoric acid into insoluble phosphoric acid in the soil under the influence of physical, chemical, and biological factors, S. SKALKIJ (*luzh. Russ. Selsk. Khoz. Gaz., 17 (1915), Nos. 33, pp. 6, 7; 34, pp. 6, 7; 36, pp. 7, 8; 37, pp. 9-11; 38, pp. 6-8; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 8, pp. 1084-1086; Jour. Soc. Chem. Indus., 36 (1917), No. 2, p. 94; Chem. Abs., 11 (1917), No. 9, p. 1237).—Field and laboratory experiments conducted at the Ploty Agricultural Experiment Station on the fixation of water-soluble phosphoric acid in April fallow soil, uncultivated land, kitchen garden soil, and forest soil are reported.* 

The soils were studied in two depths, 0 to 17.7 cm. (about 6.97 in.) and 17.7 to 35.5 cm. (about 13.98 in.). In the first series of experiments potassium nitrate at the rate of 3.605 gm. per kilogram was applied in addition to acid phosphate

at the rate of 1.3312 gm. per kilogram. In the second series part of the soil was treated with chloroform at the rate of 50 cc. per kilogram. The results are given in the following table:

Fixation of phosphoric acid soluble in water in percentages of the quantity added to the soil (1.3312 gm. of P<sub>2</sub> O<sub>5</sub> per kilogram).

Treatment.	Layer 0 to 17.7 cm.				Layer 17.7 to 35.5 cm.			
	April fallow.	Uncul- tivated land.	Kitchen garden soil.	Forest soil.	April fallow.	Uncul- tivated land.	Kitchen garden soil.	Forest soil.
First series:	Per ct.	Per ct.	Per ct.	Per ct.	Per ct.	Per ct.	Per ct.	Per et.
Total fixation (with potassium nitrate)	89. 89	87.93			92, 56	89. 87		
Total fixation (without potas- sium nitrate)	87.14	84. 04			91.64	86, 92		
Second series: Total fixation (in chloroformed soil)	87. 14	84. 04	84. 06	75, 28	91.64	86, 92	84. 11	83. 87
Physico-chemical fixation (in chloroformed soil)	84. 90 2. 24	81. 92 2. 12	82. 58 1. 48	73. 16 2. 12	89. 94 1. 70	86. 05 . 87	83. 29 . 82	83.6

It is concluded that the process of fixation of water-soluble phosphoric acid in soil depends on physical, chemical, and biological factors, and that the intensity of the total fixation is in direct relation to the cultural conditions and increases with the addition of potassium nitrate to the soil. Fixation was greater in natural soils than in chloroformed soils. The total fixation and the physical and chemical fixation were less in the arable layer, 0 to 17.7 cm., than in that lying immediately beneath, from 17.7 to 35.5 cm.

Further experiments with the bacterial flora of each of the soil samples capable of multiplying in peptonized meat bouillon led to the deduction that the quantity of these bacteria increased with the improvement of the cultural conditions of the soil.

The gases of swamp rice soils.—IV, The source of the gaseous soil nitrogen, W. H. Harrison and P. A. Subramania Aiver (Mem. Dept. Agr. India, Chem. Ser., 5 (1916), No. 1, pp. 1-31, pls. 6, fig. 1).—Continuing previous experiments (E. S. R., 36, p. 116), "it has been demonstrated that a very considerable proportion of the gaseous nitrogen normally found in swamp paddy soils is produced through the decomposition of organic matter. . . The nitrogen gas thus liberated is derived from two distinct sources, namely, (1) from the decomposable organic matter of the soil or of the green manure used, and (2) from a certain proportion of the roots of the crop which die and subsequently decompose. The production of gaseous nitrogen from soil organic matter and green manure persists throughout the growing season but is most prominent during the earlier period, whereas that derived from root decomposition is most prominent during the later stages of growth and persists after harvest time.

"There is no evidence forthcoming to show that the crop interferes with, or materially alters, the normal course of the fermentation of the soil organic matter and green manure; in fact the balance of evidence is distinctly against this theory. Under normal conditions in uncropped soils the nitrogen gas thus produced escapes from the soil into the air at a fairly uniform rate. On the other hand, that produced in cropped soils does not escape in any quantity until about the time when the plant is running up for flower. At this stage a very marked escape of gas occurs which continues up to and past harvest

time. This irregularity in the escape of the soil gases from cropped paddy soils is a purely physical phenomenon, and is caused by the roots of the crop forming, in conjunction with fine soil, a surface layer which resists the passage of the gases. The gas is thus trapped and retained in the soil until the accumulation is sufficient to cause a passage to be forced, or until the decay of some of the roots opens out such a passage."

With reference to the change in the composition of the soil gases under the action of a paddy crop, it is shown that "the physical retention of the soil gases through the action of the roots of the crop, taken in conjunction with the oxidizing action of the film, offers a simple and complete explanation of the change in composition of the soil gases under the action of the crop."

With reference to the relations of green manures to the soil and crop, the conclusion is drawn "that the nitrogen of these manures has little actual manurial value, that the crop is mainly dependent upon soil nitrogen for its support, and that green manures owe their efficiency mainly to their indirect action on the soil and by increasing root aeration." It is tentatively concluded that the practice of bringing green manure into paddy soils from external sources is preferable to growing a green crop on the soil to be puddled in, owing to the loss of nitrogen incident to the latter method.

Maintaining the nitrogen supply of the soil, A. W. Blair (New Jersey Stas. Bul. 305 (1917), pp. 5-16, figs. 8).—A general discussion of the soil nitrogen supply and its maintenance is followed by the results of an eight-year experiment in which wheat and rye were grown continuously on one-twentieth-acre plats of sandy loam soil with and without a leguminous green manure crop of cowpeas and soy beans grown between the time of harvesting the grain crop and the fall seeding of the following crop. While the yields of wheat and rye were small on all plats, those on plats receiving green manure treatment were from 50 to 100 per cent greater than those without green manure treatment.

The average yields for the legume plats and also those without legumes for the last four years were smaller than the corresponding averages for the entire eight years. This is taken as an indication that the nitrogen supply of the soil is not being maintained even where the leguminous crop is grown. The average gain in nitrogen for the legume plats for the last four years, as indicated by the amount recovered in the crop, amounted to about 15 lbs. annually.

It is suggested that farmers endeavor to maintain the nitrogen supply of their soils by growing leguminous crops either as a part of the regular rotation or as green manure crops between the main crops of the rotation as often as possible, and that for the most crops they further supplement the nitrogen thus secured by the use of a few hundred pounds of a material supplying nitrogen in a readily available form.

Fertilizers and increased production, F. T. Shutt (Amer. Fert., 46 (1917), No. 10, pp. 44, 46, 48, 52).—The author reviews Canadian experience with fertilizers, and concludes "that the exclusive use of fertilizers will neither keep up the fertility of the soil nor yield profitable returns; that it is on soils of medium rather than poor quality that a lucrative response from their employment is to be expected; that they can profitably be used to supplement the home source of fertility, farm manures; that the largest returns are not necessarily from the largest applications; and that it is on the money crop of the rotation, such as potatoes, that their application is most profitable."

Is the recovery of the nitrogen in sewage sludge practicable? W. R. COPELAND (Jour. Indus. and Engin. Chem., 9 (1917), No. 4, pp. 374-376).—Experiments conducted at the sewage testing station at Milwaukee, Wis., are

reported in which it was found "that the dried sludge has a market value upon present figures of \$9 to \$15 per ton of material containing 10 per cent moisture. The total cost of getting this product and placing it on the market will probably run from \$8 to \$12 commercially per dry ton, depending upon local conditions. For large plants this cost may possibly be reduced as a result of further experience.

"The activated sludge containing 4 per cent or more of nitrogen is much nearer a commercial possibility than the sludges obtained by the older methods of treatment, such as chemical precipitation, septic tanks, or the Imhoff process, which . . . contain only 1.5 to 3 per cent of nitrogen." The data indicate "that the recovery of the nitrogen in sewage sludge has at last been brought within the range of a commercially practicable problem."

Report on humogen, E. J. Russell (Jour. Bd. Agr. [London]. 24 (1917), No. 1, pp. 11-20).—Reviewing fully the experimental work which has been done on the subject, the author finds "no evidence that humogen possesses any special agricultural value. There is not the least indication that it is '50 times as effective as farmyard manure,' to quote an often repeated statement, and there is nothing to show that it is any better than any other organic manure with the same content of nitrogen. It is offered at present at £5 per ton in 2-ton lots; . . . [the Rothamsted] experiments give no reason for supposing that it is worth anything like so much."

The investigations have shown wide variations in the composition of the material, as well as in the results of tests of its fertilizing value. The author states that "there is no definite evidence that 'bacterization' really adds to the value of peat."

Further careful experimental work on the subject is recommended.

Grape cake as a fertilizer, L. Roos (*Prog. Agr. et Vit.* (Ed. l'Est-Centre), 57 (1916), No. 46, pp. 463-468).—It is stated that grape cake contains on the average 1 per cent of nitrogen, 0.5 per cent of potassium, 0.5 per cent of phosphoric acid, and 35 per cent of organic matter. Its fertilizing value is considered to be double that of barnyard manure.

Information on its use as a fertilizer is also given.

Comparison of four nitrogenous materials as sources of nitrogen, Z. Bonomi and G. Margheth (R. Lab. Chim. Agr. Udine, Ric. Sper. e Attiv. Spiegata, 4 (1911-1914), pp. 29-34).—Comparative tests with grain, on a soll low in nitrogen and organic matter, of calcium nitrate, sodium nitrate, ammonium sulphate, and calcium cyanamid are reported. In the order named the fertilizers are applied at rates of 8.57, 6, 4.5, and 6 kg. per hectare (7.62, 5.34, 4, and 5.34 lbs. per acre).

In grain production, the best results were obtained with calcium nitrate, followed in order by sodium nitrate, ammonium sulphate, and calcium cyanamid. In straw production, calcium nitrate showed the best results, followed in order by ammonium sulphate, sodium nitrate, and calcium cyanamid. Considering the value of the results obtained with calcium nitrate as 100, sodium nitrate, ammonium sulphate, and calcium cyanamid stood, respectively, as 42, 37, and 31.

The action of superphosphate in tests in 1913, J. M. Geerts (Meded. Proefstat. Java-Suikerindus., 6 (1916), No. 19, pp. 543-651, ftgs. 7; Arch. Suikerindus. Nederland. Indië, 24 (1916), No. 52, pp. 2065-2173, ftgs. 7).—This is an extensive report of fertilizer experiments with double superphosphate on cane soils.

It was found that double superphosphate had a distinct action on cane soils poor in phosphoric acid, but in soils rich in phosphoric acid no effect was

observed. When the supply of available phosphoric acid in the soil was low, and also when the total supply of phosphoric acid was low, an effect of double superphosphate could be expected. While the experiments on the lighter soils showed no action, those on the heavier soils showed a distinct action of double superphosphate.

It is concluded that for these soils there is a distinct limit for phosphate content. Whenever the total content was less than 0.026 per cent or the available content less than 0.009 per cent, an effect of fertilizing with superphosphate could be expected, and in some cases also where only one, more particularly the available phosphorus, was less than these limits. It is further concluded that an analysis of soil is not sufficient to determine the need for fertilization with double superphosphate. Fertilization with double superphosphate did not hasten ripening.

The extraction of potash from silicate rocks, II, W. H. Ross (Jour. Indus. and Engin. Chem., 9 (1917), No. 5, pp. 467-472, fig. 1; abs. in Amer. Jour. Sci., 4. ser., 43 (1917), No. 258, p. 485).—A study of the various methods, now including over 100 patented processes, that have been proposed for the extraction of potash from feldspar is reported in continuation of work previously noted (E. S. R., 27, p. 628).

It is concluded that the economic success of any process depends upon the recovery at the same time of some other product of value in addition to potash, the most promising by-product being cement. In experiments in which feldspar was subjected to the action of water at high temperature and pressure, there was no decomposition. When, however, the powdered feldspar was digested with water containing 1.7 parts lime at a steam pressure of from 10 to 15 atmospheres, about 90 per cent of the potash went into solution in the form of hydroxid and the residue had the composition required for Portland cement clinker.

Potash from Canadian feldspar, D. J. Benham (Canad. Chem. Jour., 1 (1917), No. 1, pp. 8-11).—The author describes a process for the extraction of potash from Canadian feldspar which it is claimed yields muriate which is almost chemically pure and permits the collection of at least 87 per cent of all the potassium chlorid vapors released from a raw mixture containing from 9.5 to 12.5 per cent of potash. "The process... consists in heating to a high temperature in a blast furnace 110 tons of a mixture of feldspar, coal, calcium, chlorid, and limestone. The limestone is used to render the slag fluid, while the chlorin of the calcium chlorid combines with the potash, forming potassium chlorid which distills over at the temperature of the blast furnace into a condenser, where it meets a current of steam in which it dissolves. By a process of evaporation and crystallization of the solution thus obtained, the salt is obtained in a high state of purity."

Report on wood and plant ashes as a source of potash, R. A. Berry (West of Scot. Agr. Col. Bul. 73 (1916), pp. 141-149).—Analyses showing the potash content of the ashes of bracken, spruce, forest hardwoods, flue dust, and miscellaneous organic substances are reported and discussed.

Bracken was found to contain 20.45 per cent of potash soluble in strong hydrochloric acid. Flue dust from blast furnaces was poor in potash, containing under 4 per cent. Spruce and forest hardwood ashes contained 11.94 and 11.79 per cent, respectively, of potash soluble in strong hydrochloric acid.

[Liming and manurial experiments] (Ann. Rpt. Agr. Expt. Stas. Assam, 1916, pp. 26-38).—This is a progress report of miscellaneous liming and manurial experiments. On an old alluvial soil it was found that annual dressings of wood ashes will replace the more expensive lime as a soil ameliorant.

The effect of fineness of division of pulverized limestone on the yield of crimson clover and lime requirement of soils, N. Kopeloff (Science, n. ser., 45 (1917), No. 1163, pp. 363-365).—Pot experiments with crimson clover on Iowa, Ohio, and Tennessee silt loams, on Virginia and California sandy loams, and on New Jersey acid muck to determine the influence of calcium oxid and limestone of 20 to 40, 60 to 80, 100 to 200, and 200+ mesh fineness when added in quantities sufficient to satisfy the lime requirement of each soil, as determined by the Veitch method are reported.

In all the soils there was an increase in the crop as the fineness of the lime-stone was increased. The yields with the 200-mesh limestone were fully one-third larger than those with the 20-mesh limestone. There was little difference between the results obtained with 200-mesh limestone and the calcium oxid. An analysis of the crops showed that as the fineness of the limestone used increased the total nitrogen increased. "The California soil, being decidedly alkaline, responded unfavorably to the application of limestone. The yield of clover as well as the total nitrogen decreased with increasing fineness of division of pulverized limestone. With the acid muck soil, however, the results were similar to those obtained with the other typical soils, i. e., an increase in fineness of division was responsible for an increase in crop yield and total nitrogen."

Determinations of the lime requirement of the soils after harvesting the clover showed that the lime requirement tended to decrease as the limestone previously applied increased in fineness. The calcium oxid was not so effective in this respect as was the 200-mesh limestone.

Limestones of Michigan, R. A. SMITH (Mich. Geol. and Biol. Survey Pub. 21, Geol. Ser. 17 (1916), pp. 103-311, pls. 10, figs. 13).—This report embraces (1) a discussion of the character, origin, and classification of limestones; (2) an outline of the geology of the limestone formations of Michigan; (3) their uses; and (4) descriptions of the occurrence, character, development, and economic possibilities of the limestone beds of the different counties of the State.

Agricultural lime, M. F. Miller and H. H. Krusekopf (Missouri Sta. Bul. 146 (1917), pp. 25, flgs. 7).—This is a popular review of experience in liming Missouri soils, with a description of the limestone resources of the State.

It is stated that approximately two-thirds of the samples of Missouri soils examined at the station have shown more or less need for lime. About one-fourth of these have shown a lime requirement of 2 tons or over per acre to a depth of 7 in. Ground limestone is considered to be as a rule the cheapest form to apply.

"Missouri has much limestone suitable for agricultural purposes. The most extensive region of high-grade, high calcium stone extends from southwest Missouri in a northeasterly direction to the Missouri River, spreading out and covering the eastern part of the State both north and South. The Ozark limestones contain much magnesium, and while these are not usually considered so desirable as the high calcium stones they are yet very satisfactory for agricultural purposes."

Tabulated analyses of agricultural lime (Off. Bul. Bd. Agr. Ohio, 8 (1917), No. 1, pp. 62-64).—This section of the report contains the results of actual and guaranteed analyses of 40 samples of limestone, calcium carbonate, quicklime, and hydrated lime collected for inspection in Ohio during 1916.

Inspection of commercial fertilizers, 1916, P. F. Trowbridge (Missouri Sta. Bul. 145 (1917), pp. 41, ftg. 1).—This bulletin contains the results of actual and guaranteed analysis of 331 samples of fertilizers and fertilizing materials collected for inspection in Missouri during 1916, together with the results of tests of the relative value of 163 samples of limestone for correcting soil acidity. A list of brands registered for sale in the State for 1917 is also given.

[Commercial fertilizer analyses] (Off. Bul. Bd. Agr. Ohio, 8 (1917), No. 1, pp. 65-82).—This section of the report contains the results of actual analyses of 76 samples of mixed fertilizers, 5 samples of bones, and 4 samples of unmixed fertilizing materials collected for inspection in Ohio during 1916, together with a list of brands of fertilizers licensed from January 1 to February 1, 1917.

Fertilizer registrations for 1917, C. S. CATHCART (New Jersey Stas. Bul. 304 (1917), pp. 5-42).—This bulletin contains the list of fertilizer registrations received in New Jersey for 1917 up to January 22.

## AGRICULTURAL BOTANY.

Periodicity in transpiration, Sophie J. Wilkie (Trans. and Proc. Bot. Soc. Edinb., 27 (1915-16), pt. 1, pp. 59-64, figs. 2).—The author has employed the apparatus previously described (E. S. R., 34, p. 729) in tests with Pinus sylvestris, Opuntia occidentalis, and Lilium rubrum as herein detailed. She has found that under ordinary conditions there is a daily periodicity in transpiration by these plants, which show also individual differences in this respect, transpiration being active but erratic in darkness.

Comparison of the hourly evaporation rate of atmometers and free water surfaces with the transpiration rate of Medicago sativa, L. J. Briggs and H. L. Shantz (U. S. Dept. Agr., Jour. Agr. Research, 9 (1917), No. 9, pp. 277-292, pls. 3, figs. 4).—The authors report a study of the individuality of evaporating surfaces as related to the hourly transpiration rate, employing M. sativa and the four types of porous-cup atmometers designed and used by Livingston (E. S. R., 33, p. 320; 34, pp. 34, 521), evaporation tanks which are described, and a filter-paper evaporimeter of special design. The measurements were made at Akron, Colo., during a period of hot, dry weather in July, 1916.

The various atmometers, though differing widely in form, gave graphs which are similar in their characteristics. No very close correspondence was observed between the hourly transpiration rate of alfalfa and the hourly evaporation rate, as given, of any of the systems employed. The departure of the hourly evaporation rate of the porous-cup atmometer from the hourly transpiration rate of alfalfa is considered to be due largely to the increase in evaporation over transpiration during the night, to the sensitivity of the atmometers to changes of wind velocity (not accompanied by like changes in transpiration), and to deficient response by the atmometers to changes in solar radiation.

Lack of high correlation between evaporation and the hourly transpiration rate does not necessarily involve low correlation on a daily basis.

The plant may not respond freely to its environment, but that fact is not considered proved by a departure of relative transpiration rate from evaporation rate in an arbitrarily chosen physical system.

The relationship existing between the oxidase activity of plant juices and their hydrogen ion concentrations, with a note on the cause of oxidase activity in plant tissues, H. H. Bunzel (Jour. Biol. Chem., 28 (1916), No. 1, pp. 315-333. flgs. 3).—In continuation of a general body of work begun some years ago, reports on which have been noted as given by the author (E. S. R., 27, p. 9; 29, p. 48; 31, p. 748) or by True and Stockberger (E. S. R., 36, p. 127), the author undertook to study the oxidase activities of various plant tissues in different hydrogen ion concentrations, hoping that such study might throw some light on the nature of the acid effect and furnish further data on the comparative behavior of oxidases from different sources. An account is given of the methods employed. The results as tabulated are considered to corroborate in a quantitative way the findings of other experimenters cited

on the inhibition of oxidase by acids, no experiments being made in alkaline solutions owing to the inadequacy of the technique at present available.

The experiments, while not sufficiently numerous to establish clearly the relationship between oxidase activity and hydrogen ion concentration, suggest the agency of two factors, the direct destructive effect of acidity on the active matter and the retardation of oxidation rate by the hydrogen ions. These factors may prove to be easily separable.

It appears that the hydrogen ion concentration for each type of plant material covers only a comparatively narrow range, a fact which may prove to be important. It would seem that the nature of the material related to oxidase activity is identical in closely related plants.

Just what particular agency is responsible for oxidase activity is not yet determined, although it is widely distributed in nature. Active and inactive modifications probably exist side by side, some characteristics noted strongly suggesting the agency of colloids.

Evidence of the action of oxidases within the growing plant, J. H. Kastle and G. D. Buckner (Jour. Amer. Chem. Soc., 39 (1917), No. 3, pp. 478-482).— The authors have attempted to establish the presence of oxidases and available oxygen in growing plants. Sweet corn and okra were injected with phenolphthalein, then sectioned and tested with alkali, which showed the pink coloration of phenolphthalein mostly above the point of injection and in some instances extending nearly to the leaf tips. The reagents seem to have traveled along the vascular bundles, spreading in some cases into the neighboring cells. The facts observed are considered to show the occurrence of oxygen and oxidation in the living cells in both monocotyledons and dicotyledons.

The occurrence and physiological significance of flavone derivatives in plants, K. Shibata, I. Nagai, and M. Kishida (Jour. Biol. Chem., 28 (1916), No. 1, pp. 93-108, pl. 1).—The authors, continuing the work previously noted (E. S. R., 36, p. 329) on flavone derivatives and their relations to other bodies, such as anthocyanin, have carried on a series of studies on the occurrence and the physiological and biological significance of such substances in plants.

It is claimed that a general occurrence of flavone derivatives in plants is now established, but that these, with a few exceptions noted, are limited almost exclusively to the epidermis and the peripheral parenchymatous layer of the aerial parts. It is assumed that flavone derivative solutes in cell sap are important as alding absorption of ultraviolet waves and as thus protecting the protoplasm and its biochemical activities. This assumption is said to have been supported by observations on plants from alpine and tropical regions where the sun's rays are intense, the plants grown in strong insolation being always rich in flavones except in case of those protected by anatomical and morphological peculiarities. Green leaves of deciduous trees, destined to produce anthocyanin pigment in autumn, are said to contain considerable flavone, the production of autumnal anthocyanin color being due to the reduction of such flavones and initiated by physiological conditions at the end of the growing season.

The acidity of plant cells as shown by natural indicators, A. R. Haas (Jour. Biol. Chem., 27 (1916), No. 1, pp. 233-241).—The author has endeavored to ascertain to what extent natural indicators in living cells can be utilized to determine their reaction (the actual acidity of the dissociated hydrogen ions as contrasted with the total acidity, which includes both dissociated and undissociated hydrogen ions). He has found that the reaction of the sap in some entirely normal cells may be decidedly acid and that a blue color in living cells does not necessarily indicate an alkaline reaction, also that in a dying cell a considerable alteration of reaction may occur.

Germination of seeds of Lepidium sativum in solutions of electrolytes, P. Lesage (Compt. Rend. Acad. Sci. [Paris], 164 (1917), No. 2, pp. 119-121).— Having observed in the work previously noted (E. S. R., 37, p. 26) that the osmotic pressure of the solution in which seeds of L. sativum were being soaked plays an important part in germination, and having entered upon a study of the part played by dissociation in that connection, the author here discusses some of the mathematical and practical phases of that work.

The influence of different media on the histology of roots, SOPHIE J. WILKIE (Trans. and Proc. Bot. Soc. Edinb., 27 (1915-16), pt. 1, pp. 76-78, pl. 1).—This is a short note on the differences found to exist in the anatomical structure of roots of Monstera deliciosa grown in air, soil, water, wet gravel, and damp soil.

It was found that the development of the absorptive layer varies inversely, and the mechanical tissue directly, with the humidity of the medium. There is no variation in the size of the intercellular spaces of the fundamental tissue, excepting the presence of lacunæ in the cortex of the water roots.

The permeability of living cells to acids and alkalies, A. R. Haas (Jour. Biol. Chem., 27 (1916), No. 1, pp. 225-232).—In view of the fact that metabolism is strongly influenced by changing the chemical reaction of the protoplasm, the author has made a study of the penetration of the cell by reagents, employing as indicators petals of Browallia speciosa and Pelargonium, the perianth of the hyacinth, and the root of the red radish, which prove to be well adapted to this purpose. Differences noted in the relative rate of penetration by the hydrogen ion on employment of different methods are thought to be explainable by the dissociation of the acids concerned.

Salt antagonism in gelatin, W. O. Fenn (*Proc. Nat. Acad. Sci., 2* (1916), No. 9, pp. 534-538, flgs. 3).—Discussing previous contributions with explanations regarding observed salt antagonisms, the author presents his own hypothesis, which is said to be supported by experimentation on gelatin. This is that anions antagonize cations in their effects upon organisms, the point of maximum antagonism being an isoelectric point at which the amount of alcohol needed for precipitation is at a minimum and the aggregation or amount of precipitation at a maximum.

Similarity in the behavior of protoplasm and gelatin, W. O. Fenn (*Proc. Nat. Acad. Sci.*, 2 (1916), No. 9, pp. 539-543, figs. 2).—Discussing the above and other investigations, the author concludes that if we assume that the effect of time in the Laminaria experiments of Osterhout (E. S. R., 32, p. 728) is to increase the concentration of the salts in the cells of the tissue, a close analogy to these experimental results is found in gelatin to which sodium hydroxid has been added.

Tolerance of fresh water by marine plants and its relation to adaptation, W. J. V. OSTERHOUT (Bot. Gaz., 63 (1917), No. 2, pp. 146-149).—The author has followed up studies previously noted (E. S. R., 30, p. 130) regarding the effects of distilled water on protoplasm. He has found that remarkable differences exist between plants, and even between different cells of the same plant, with respect to their tolerance of fresh water. These differences may prove to be of significance in connection with adaptation.

In case of Polysiphonia, many cells are killed by exposure to pure distilled or fresh water for less than one minute. Instances are discussed of remarkable tolerance by plants naturally, accidentally, or experimentally subjected to great and quick alterations of salinity in the water. It is supposed that some characters attributed to adaptation may have been present from the beginning and that they may have been due originally to entirely different causes. The fact that leaf cells, as compared with root cells of the same plant, withstand

a much longer exposure to fresh water is considered significant. Suggestions are made that some protoplasm may part more readily than other with certain salts with which it may be chemically or mechanically united, and that the less tolerant protoplasm may consist more largely of such substances as globulins or other colloids, which undergo a change of state as soon as the concentration of the salts falls below a certain limit.

Copper in the flora of a copper-tailing region, W. G. BATEMAN and L. S. Wells (Jour. Amer. Chem. Soc., 39 (1917), No. 4, pp. 811-819).—Plants growing in a copper-tailing region were found to contain copper, arsenic, antimony and zinc, the amounts of copper ranging from 0.0046 to 0.621 per cent. Larger quantities were present in the dead than in the living tissue and in the bark than in the other parts of the plant.

It is noted that "many plants are unable to adapt themselves to this novel factor of environment, while others flourish in spite of it, thus showing a decided selective activity."

Models to illustrate segregation and combination of Mendelian characters, H. M. CHIBBER (Agr. Jour. India, Indian Sci. Cong. No., 1916, pp. 80-85, figs. 2).—This paper describes a scheme for demonstrating the behavior of hereditary characters that conform with the Mendelian principles. The dominant determiners are represented by colored beads, while the recessive determiners are represented by beads identical in size and shape but colorless. The method of demonstrating the composition of different zygotes and of their gametes is illustrated with reference to one, two, and three characters, respectively. The demonstration of the phenotypic composition is also illustrated.

The probable error of a Mendelian class frequency, R. Pearl (Amer. Nat., 51 (1917), No. 603, pp. 144-156).—In view of the growing need for adequate and clearly understood tests for the statistical significance of differences between expectation and observed results in Mendelian experimentation, the author offers a method supplementary to those in use of calculating and expressing the errors, due to random sampling, of a Mendelian class frequency. The method consists essentially in expressing each expected frequency as the probable quartile limits, determined from the ordinates of a hypergeometrical series, for that class frequency in a supposed second sample of the same size as the observed sample drawn from the same population. Simplifications of method are suggested and illustrated.

Note on the inheritance of crossability, W. O. BACKHOUSE (Jour. Genetics, 6 (1916), No. 2, pp. 91-94).—The author found that in the progeny of a hybrid wheat crossed with rye there was a segregation of crossability. The data here obtained from this and other crossings described are considered to justify caution in ascribing importance to the production and fertility of hybrids as a guide to relationship. It is considered as very probable that the deciding factor as to whether two individuals will hybridize or not may depend upon one simple Mendelian factor.

The results of hybridization in Salix, S. IKENO (Bot. Mag. [Tokyo], 30 (1916), No. 357, pp. 316-320).—Experimentation, including artificial hybridization since 1910 between S. purpurea multinervis and S. purpurea gracilistyla, is said to have shown that the hybrids are not always constant. A certain amount of splitting was revealed, somewhat obscured by the failure of some of the plants to live, so that the question as to Mendelian behavior in this respect is not yet settled.

Evolution by means of hybridization, J. P. Lorsy (The Hague: Martinus Nijhoff, 1916, pp. X+166, figs. 2).—Discussing some evidences and views which have been offered regarding the problems and methods of organic evolution, the author claims that crossing is the cause of the origin of new types which

are perpetuated by heredity, natural selection being the cause not of their origin but of their gradual extinction. It is considered correct, in a sense, to say that species are related to one another in the same way that human brothers or cousins are, being in each case simply separates resulting from a previous crossing.

The bearing of some general biological facts on bud variation, E. M. East (Amer. Nat., 51 (1917), No. 603, pp. 129-143).—The author, dealing with the possible relation to bud variation of such conditions as environment, mutilations, diseases, and changes in food supply, states that bud variations are comparable to seed variations in their nature and in the abundance of types produced thereby, but handicapped by the fact that recombinations of variant characters are possible only in case of sexual reproduction. It is held that environment must have been an immense factor during the long periods involved in organic evolution, but its effects are shown so infrequently that it may be neglected for the practical purposes of plant breeding. It would not, however, be safe to deny importance to bud variation as an adjunct to plant breeding.

Mendelian factor differences v. reaction system contrasts in heredity, I, II, T. H. Goodspeed and R. E. Clausen (Amer. Nat., 51 (1917), Nos. 601, pp. 31-46; 602, pp. 92-101).—In this work, which besides listing related contributions deals with a number of facts and conclusions drawn from contributions by Goodspeed, alone or with others (E. S. R., 34, p. 136; 37, p. 225), it is stated that Nicotiana sylvestris, when crossed with varieties of N. tabacum, gives an F<sub>1</sub> hybrid which is a replica, on a large scale, of the tabacum variety employed. Such hybrids produce a small number of functional ovules which represent the sylvestris and tabacum extremes of a recombination series, most members of which fail to function because of mutual incompatibility of the elements of the two systems. Back crosses with sylvestris give both sylvestris and aberrant forms, of which the former only are fertile and breed true. Back crosses with tabacum produce apparently only tabacum forms, some of which are fertile and breed true.

The authors reach the general conclusion that Mendelian factors may be considered as making up a reaction system, the elements of which exhibit more or less specific relations to one another. Strictly Mendelian results are to be expected only when the contrast is between factor differences within a common Mendelian system, as ordinarily in varietal hybrids. When distinct reaction systems are involved, as in species crosses, the phenomena are to be regarded as a contrast between systems rather than between specific factor differences. Sterility in such cases depends upon nonspecific incompatibility between elements of the systems involved, and its degree depends upon the degree of incompatibility rather than upon the number of factors. The consequences of the application of such a conception to the complex type of behavior in Œnothera are pointed out and the suggestion is made that the type of behavior exhibited by Œ. lamarckiana and its segregants in hybridization may be referred to such complex system interactions.

**E**nothera mutants with diminutive chromosomes, ANNE M. LUTZ (Amer. Jour. Bot., 3 (1916), No. 9, pp. 502-526, pl. 1, flgs. 7).—In this report, the first of a projected series of three on studies continuing for several years in Europe and America and dealing with somatic chromosome number in mutants of the lamarckiana group of Enothera, the author considers the 14-chromosome mutants, the 14<sup>+1</sup>-chromosome mutants and offspring of certain hybrids, the origin of the small chromosome and its fate in succeeding generations, chromosomal individuality as evidenced by the small chromosomes, and some observations on E. rubrinervis.

Root cuttings, chimeras, and sports, W. Bateson (Jour. Genetics, 6 (1916), No. 2, pp. 75-80, pl. 1).—The author states that some unsuspected plants are really periclinal chimeras, having an outer layer or cortex distinct in genetic composition from the inner core, and that whenever plants grown from root cuttings differ from those grown from corresponding stem cuttings, it may be inferred, at least provisionally, that the plant is a periclinal chimera. Some studies have been undertaken and are still in progress with Bouvardia, some doubles of which are said to give singles from their root cuttings, differences in color appearing also in several instances.

Fasciation in Pharbitis hederacea, Y. Yamaguchi (Jour. Col. Sci., Imp. Univ. Tokyo, 39 (1916), Art. 2, pp. 56, pls. 2, figs. 3).—The author, reporting a study of P. hederacea, states that Knop's solution in 1, 2, and particularly 5 per cent strength favored the production of fasciation. The higher concentrations hindered greatly the development of the fasciated plants, while the normal plants were but little retarded thereby. Darkness had little effect upon the development of fasciation and topping produced no fasciation in normal plants. Longitudinal splitting at the top of the stem resulted in slight fasciation, as did removal of the blooms, the same treatment giving uncertain results when applied to the leaves and tending to recovery of fasciated plants when applied to the roots.

The woody structure was looser and less developed in fasciated plants, with a relatively greater development of the vascular bundles and a diminution of size with increase in length of the cells. This phenomenon appears to be hereditary, showing from the earliest stages. The production of fasciation, so far as its mechanical phases are concerned, is due to the early coalescence of the leaf stalk with the plant stem in conjunction with leaf growth in the early stages of development.

Plant succession.—An analysis of the development of vegetation, F. E. CLEMENTS (Carnegie Inst. Washington Pub. 242 (1916), pp. XIII+512, pls. 61, figs. 51; rev. in Jour. Ecology, 4 (1916), No. 3-4, pp. 198-204).—This book constitutes the general part of a monograph on Rocky Mountain vegetation, a study of which has been in progress since 1899. The general principles herein set forth are an outgrowth of the treatment in the contributions previously noted (E. S. R., 15, p. 955; 19, p. 529), the original concepts in which have been confirmed and generalized by the studies since carried on.

It is thought that the earlier concept of the formation as a complex organism with a characteristic development and structure in harmony with a particular habitat is fully justified, representing really the only possible complete and adequate view of vegetation. This concept has been broadened and definitized by the recognition of the developmental unity of the habitat, so that formation and habitat are regarded as the two inseparable phases of a development which terminates in a climax controlled by climate. All vegetation has thus been developmentally related, every climax formation having its phylogeny as well as its ontogeny. Essentially the same processes or functions of vegetation have held throughout geologic time, so that it is possible to sketch the succession of plant populations throughout eras and periods, organizing in a tentative fashion the new field of paleoecology.

A bibliography is appended.

Polar bear cacti, O. F. Cook and Alice C. Cook (Jour. Heredity, 8 (1917), No. 3, pp. 113-120, figs. 6).—Opuntia floccosa, found on exposed slopes of the bleak plateaus of the Andes of southern Peru, is described in connection with environmental relations as regards protection against direct sunshine and cold. It is suggested that there may be a real analogy between these cacti and the

animal from which they are named as regards adaptation to extreme special conditions.

A quantitative, volumetric, and dynamic study of the vegetation of the Pinus tæda belt of Virginia and the Carolinas, R. M. HARPER (Bul. Torrey Bot. Club, 44 (1917), No. 1, pp. 39-57, fig. 1).—This is an account of a very rapid survey of the P. tæda belt of the Atlantic coastal plain as regards its boundaries, topography, hydrography, soils, climate, and vegetation, giving lists of plants observed with estimated percentages of the several species.

Meadow vegetation in the montane region of northern Colorado, E. L. Reed (Bul. Torrey Bot. Club, 44 (1917), No. 2, pp. 97-109, ftg. 1).—The results of studies made during two summer seasons are embodied chiefly in descriptions of seven plant societies of meadows of the Boulder Park region, at Tolland, in northern Colorado, with an altitude of 2,710 meters (8,891 ft.). Societies of the lower montane region are indicated and the different characteristics of the subalpine meadows are also briefly discussed. A list of the meadow plants of Boulder Park with their frequency and soil moisture index is also given.

Taxonomic botany and the Washington botanist, A. S. HITCHCOCK (Jour. Wash. Acad. Sci., 7 (1917), No. 9, pp. 251-263).—This is a plea for a better utilization of the opportunities in the vicinity of Washington, D. C., as regards observation and taxonomic study of local flora.

# FIELD CROPS.

Forage and root crops, C. S. KNIGHT (Nevada Sta. Bul. 86 (1917), pp. 3-20, figs. 13).—Variety tests with alfalfa, corn (for silage), sorghum, and potatoes; irrigation tests with alfalfa and red clover; field tests of sweet clover, Sudan grass, and beets and mangels; and tests of forage crops for seed and hay production are reported.

Australia alfalfa No. 23753 was first of 66 varieties with a yield of 6,920 lbs. and North Dakota No. 27247 second with 6,875 lbs. of cured hay per acre. The proportion of leaves to the entire plant was 36.8 and 36.5 per cent, respectively. Nevada No. 6 was lowest with a yield of 2,100 lbs. The proportion of leaves to stems for all the varieties tested varied from 48.5 per cent in France No. 12694 to 30 per cent in Media No. 16400, although the yields of the two varieties named were identical, 3,004 lbs. of hay per acre.

Improved Learning corn gave the highest average yield of silage per acre, 11.3 tons, for the 4-year period 1913 to 1916. Wisconsin Yellow Dent, with a yield of 8.5 tons, was lowest. No variety has matured grain.

The sorghums did not mature seed and were considered inferior to corn for silage purposes. Broom corn produced a heavy brush, but did not mature seed.

The Great Divide and Burbank varieties of potatoes, with average yields of 12,161 and 10,204 lbs. per acre, respectively, have given the best results in potato variety tests for the 4-year period 1913 to 1916.

Irrigation tests with alfalfa and red clover included 6, 9, and 12 in. applications of water at three successive stages of wilt. With the advance in the wilting stage, the average variations in alfalfa for a 3-year period were from 64 to 21 in. in total irrigation, 83.9 to 76.4 per cent in total water content, 37.3 to 43.2 per cent in proportion of leaves to stem, 6.68 to 4.41 tons in yield per acre, and 1.29 to 2.05 tons in yield per acre-foot of water. The heaviest yield per acre, 7.32 tons, was secured with the heaviest total irrigation of 72 in., but the yield per acre-foot of water was only 1.23 tons. These results indicate that the most economical use of water favors 12-in. applications (with a total irrigation of about 36 in.) between the last two stages of wilting, this

resulting in an average yield of 5.7 tons per acre and of 1.85 tons per acre-foot of water. In all three stages the 6-in applications gave the lowest and the 12-in the highest yields, with but little variation in yield per acre-foot of water. A gradual decrease in yield was noted with the same applications made as the wilting stage advanced. Alfalfa responded better than wheat and potatoes to heavy applications of water.

The highest clover yield, 6.97 tons per acre, was secured from a total of 57 in. of water in 12-in. applications (the first application being 9 in.), with a yield of 1.47 tons per acre-foot of water. The lowest yield, 2.71 tons, was secured with four 6-in. irrigations and gave 1.35 tons per acre-foot of water. The results indicate that clover can not be allowed to reach the wilting stages without a material decrease in the yield of hay. The nitrogen content varied inversely with the total yield of forage per acre.

Sudan grass yielded 3.8 tons of forage and 1,912 lbs. of seed per acre in the 1916 trials and is especially recommended for seed production for well-drained soils of Nevada.

Field trials with root crops gave average yields of 15.73 tons of roots for Our Ideal mangels and 12.06 tons for sugar beets, with an average sugar content of 4.5 and 19.5 per cent, respectively. In date-of-planting tests with sugar beets the yield varied from 20.79 and 20.35 tons for beets planted April 23 and 30, respectively, to 4.79 tons for beets planted July 2. Nevada-grown sugar beet seed yielded at the rate of 20.9 tons per acre, with 19.5 per cent sugar and 82.1 per cent purity of juice, while seed of Russian origin produced 20.8 tons per acre, with 17.5 per cent sugar and 75.3 per cent purity of juice.

Sudan grass, beans, and field peas were compared for seed production. The Kaiser field pea, with an average yield of 1,667 lbs. per acre, was highest and California Mexican Large bean lowest, with 505 lbs. Sudan grass gave an average yield of 1,506 lbs. A similar test with Sudan grass, millet, and field peas for hay production resulted in an average yield of 2.7 tons per acre with Siberian millet, while Bangalia field pea was lowest, with 1.27 tons. Sudan grass gave an average yield of 2.5 tons and Green Canada field pea an average yield of 2.1 tons per acre.

Field crops for late planting, C. S. KNIGHT (Nevada Sta. Bul. 88 (1917), pp. 15, figs. 5).—The value of wheat and oats for hay, and of potatoes, sugar beets, Sudan grass, and millet for late planting, due to a late, cold spring, is discussed in a popular manner, including cultural directions.

[Field crops] (Izv. Khartov. Oblast. Selsk. Khoz. Opytn. Sta., Otd. Polevod., No. 3 (1915), pp. XII+112, fig. 1).—Field experiments conducted at the Kharkov Experiment Station in 1912, 1913, and 1914 are reported, and include fertilizer, manurial, variety, and cultural tests with rye, corn, sorghum, spring wheat, winter wheat, barley, oats, millet, and potatoes.

[Field crops], E. A. Nobbs (Rhodesia Agr. Jour., 13 (1916), Nos. 4, pp. 474-488; 5, pp. 659-672, pl. 1).—Field tests with varieties, fertilizers, and cultural methods on various crops at the Gwebi Experiment Farm for the season of 1915-16 are reported.

[Field experiments], A. W. K. De Jong and C. VAN ROSSEM (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Agr. Chem. Lab., No. 12 (1916), pp. 150, pl. 1, figs. 41).—This is a detailed report of field experiments in the testing of fertilizers, stable manure, and crop rotations for the year 1914-15.

[Field crops] (Rpt. Nagpur Expt. Farm [India], 1915, pp. 21, 22).—A glossary of the botanical, English, and vernacular names of a number of crops grown in India is given, together with several local agricultural terms and their meanings.

[Registration of varieties], E. G. MONTGOMERY, C. G. WILLIAMS, and H. K. HAYES (Jour. Amer. Soc. Agron., 8 (1916), No. 6, pp. 391-394).—This is the report of the committee on varietal nomenclature of the American Society of Agronomy previously noted (E. S. R., 36, p. 198). A suggested form of application for registration of varieties of winter wheat is included.

[Field crops] (Proc. Amer. Seed Trade Assoc., 34 (1916), pp. 125, pl. 1).—The following papers relating to field crops were read at the thirty-fourth annual convention of the American Seed Trade Association: The Evolution of Corn Growing and Feeding in the Northwest, by A. K. Bush; Farmers' Associations, by W. D. Weedy, with special reference to the dissemination of pedigreed seed; Report of Committee on Experiment Stations, by L. L. Olds; Report of the Committee on Nomenclature, by H. G. Hastings; and The Vegetable Growers' Attitude Toward Nomenclature, by C. E. Durst.

[Field crops] (Proc. Dry Farming Cong., 10 (1915), pp. 69-126, 207-238, figs. 3).—At the tenth annual session of the International Dry-farming Congress the following papers relating to field crops were presented: High Altitude Crops, by T. S. Parsons; Grasses in Relation to Dry Farming, by C. V. Piper; Dry Farming in Western Canada, by J. Bracken; Cultivation to Conserve Soil Moisture, by W. W. Burr; Effect of Soil Alkali on Dry-farm Crops, by F. S. Harris; Dry-land Agriculture Investigations in the Great Plains Area, by E. C. Chilcott; and Arizona Indian Agriculture, by A. M. McOmie.

Notes on dry farming in the following countries were given by their respective representatives: Colombia, Nicaragua, Australia, South Africa, China, Greece, Russia, Belgium, Sweden, Roumania, Guatemala, Iceland, and Argentina.

Dry farming in Colorado, A. Kezer (Colorado Sta. Bul. 227 (1917), pp. 3-40, figs. 12).—General principles of dry-land farming applicable to Colorado conditions are discussed in detail, and crops deemed suitable for dry farming recommended and their production described.

Grasses under drought conditions at Hawkesbury Agricultural College, W. D. Kerle (Agr. Gaz. N. S. Wales, 27 (1916), No. 10, pp. 694-697, figs. 3).— Brief notes are given on the behavior of certain grasses under extreme drought conditions during the year 1915 and part of 1916. The precipitation for the year ending December 31, 1915, was 16.725 in., the lowest in 51 years; and for the year ending May 31, 1916, only 13.195 in. The grasses noted are Eragrostis curvula, Chloris gayana, Andropogon intermedius, E. leptostachya, Paspalum dilatatum, Anthistiria avenacea, Pollinia fulva, and Andropogon sorghum.

Artificial reseeding of range lands, A. W. Sampson (Nat. Wool Grower, 6 (1916), No. 11, pp. 23-25, figs. 5).—This is a discussion of the results obtained in various tests undertaken by the U. S. Forest Service in reseeding range lands in restricted localities extending from Canada to Mexico.

Fall sowing is recommended and the trampling of the seed by sheep was found to be sufficient to work it into the soil. Successful seedings were obtained with timothy, smooth brome grass, perennial rye grass, Italian rye grass, redtop, and Kentucky blue grass, in the order named. Of the clovers, white clover gave the best returns. The moisture conditions of the land will determine to a large extent the plants to be seeded, and with that in view the following recommendations are made: Mixture for wet lands, redtop 5 lbs., timothy 3 lbs., Italian rye grass 3 lbs., and alsike clover 2 lbs. per acre; mixture for moist lands, timothy 3 lbs., orchard grass 5 lbs., Kentucky blue grass 5 lbs., and white clover 2 lbs.; and mixture for medium moist lands, smooth brome grass 6 lbs., timothy 4 lbs., slender wheat grass 5 lbs. Attempts at seeding the drier lands have not been successful.

Cereal experiments, A. C. Tonnelier (Experiencias sobre Cereales. Buenos Aires: Min. Agr., 1914, pp. 239, figs. 38).—Field tests with wheat, barley, rye, and oats from 1910 to 1913, inclusive, are reported, including general notes on variety tests with each cereal for 1910 and 1911 (pp. 5-75); notes on variety tests for 1911 and 1912 (pp. 79-133); notes on fertilizer and cultural experiments with wheat and barley for 1911 and 1912 (pp. 137-169); and notes on variety tests with wheat, barley, and rye for 1912 and 1913 (pp. 173 to 239).

Seed grain inspection and crop reports, 1915–16, J. J. GABLAND (Ann. Rpt. Wis. Agr. Expt. Assoc., 14 (1916), pp. 11–16).—The reports of members of the Wisconsin Agricultural Experiment Association on the yields of pedigree grains grown in 1915 show that pedigreed barley yielded 5.5 bu. per acre in excess of the United States average, pedigreed oats No. 1 9.3 bu. and pedigreed winter rye 4.4 bu. over other varieties, and pure-bred corn (Wis. No. 7) 23 bu., select winter wheat 10.4 bu., and spring wheat 10 bu. over the United States averages. Data are also presented from experiments conducted by members of the association on rates of seeding, drilling v. broadcasting, and spring v. fall plowing.

Some effects of legumes on associated nonlegumes, M. W. Evans (Jour. Amer. Soc. Agron., 8 (1916), No. 6, pp. 348-357, pls. 2).—This is a further study of some of the effects of legumes on nonlegumes growing in a mixture with them. The experiments described were performed during 1912, 1913, 1914, and 1915 at the timothy breeding station at New London, Ohio, which is conducted cooperatively by the U. S. Department of Agriculture and the Ohio Experiment Station. The leguminous plant used was clover (Trifolium pratense and T. repens), while timothy (Phleum pratense), redtop (Agrostis alba), and Kentucky blue grass (Poa pratensis) were grown alone and in mixture with the clover.

The following table shows the percentage of increase in the protein content and length of leaf in the grasses grown with clover over those grown alone:

Percentage of increase in the protein content and in the length of leaf growth in grasses grown with clover over grasses grown alone.

Kind of grass.	Protein (N×6.25).	Length o. leaf.
Timothy grown in lawn plat Timothy grown in field. Redtop. Kentucky blue grass	Per cent. 18. 89 7. 68 9. 48 16. 03 13. 02	Per cent. 21. 27 19. 41 13. 21 20. 13

Timothy plats receiving ammonium nitrate showed a somewhat greater increase in percentage of protein in the grass over those plats where the grass was grown in mixture with clover.

Clippings from plats where grass was grown in mixture with clover showed a larger proportion of green leaves and a correspondingly smaller proportion of dry brown leaves than clippings from plats where grass was grown alone.

Soy beans and cowpeas in Illinois, W. L. Burlison and O. M. Allyn (Illinois Sta. Bul. 198 (1917), pp. 20).—The adaptability and production of soy beans and cowpeas in central and southern Illinois are briefly discussed, with a report of extensive variety tests at Urbana (Champaign Co.) and Fairfield (Wayne Co.).

The soy bean appears to be much better suited to Illinois conditions than the cowpea, except on poor, unfertilized, sour soil in southern Illinois, where the latter may be more hardy.

A seeding rate of from 30 to 40 lbs. per acre for soy beans is recommended when the beans are planted in rows, with a rate of from 1 bu. to 6 pk. when sown broadcast.

The variety tests included a comparison of yields of seed, hay, and straw. Recommendations of soy bean varieties for central Illinois include Haberlandt, Hong Kong, Chestnut, Amherst, Ebony, Sherwood, Meyer, and Nuttall for seed production. Ebony is a consistent-yielding, medium late, standard variety, while Medium Yellow, although not a high-yielding variety, is early and is recommended for planting when winter wheat is to follow soy beans. The two last-named varieties are considered the best for southern Illinois conditions. The agronomic characteristics of 27 varieties of soy beans are listed in tabular form.

In variety tests with cowpeas for seed production Extra Early Black Eye for central Illinois and Michigan Favorite for southern Illinois gave the best results. Cowpea tests were abandoned at Urbana in 1909, due to the superiority of soy beans. At Fairfield the range of average yields of soy beans was from 6.5 to 16 bu. per acre, while the range of cowpeas was only from 3.4 to 7.2 bu. per acre.

A test of soy beans grown in rows 24 in. apart and cultivated, at Fairfield, gave a 3-year average yield of 14.4 bu., as compared with a yield of 15.5 bu. from beans sown in rows 8 in. apart and not cultivated. The highest average yields of beans were secured for two consecutive years from a row spacing of 24 in. as compared with spacings of 32 and 40 in.

The dry-matter content of field-cured and green forage, A. C. Arry (Jour. Amer. Soc. Agron., 8 (1916), No. 6, pp. 358-363, pl. 1).—This is a comparison of the determination of the yields of alfalfa and other forage crops by weighing the field-cured hay with weighing the crop green. The data were obtained under field conditions from a large number of plats on the university farm, Minnesota College of Agriculture. The crops of 1915 were weighed and sampled as soon as cut and are compared with those of 1914, which were weighed and sampled when field-cured.

The coefficient of variation appears to be the most satisfactory basis for comparison and is given, together with the mean of the dry-matter percentages and the standard deviations. Data are given for three cuttings of alfalfa, two cuttings of timothy and clover mixed, and one cutting of sweet clover for each year.

The alfalfa and timothy and clover plats were less variable in dry-matter content in 1914 than when weighed as soon as cut in 1915. Sweet clover was more variable in dry-matter content when weighed and sampled in the field-cured condition than when weighed and sampled as soon as cut. A more accurate estimate of the weights of alfalfa and timothy and clover mixed was secured from the weights based on the field-cured hay than on the crop cut green. Sweet clover showed a higher moisture content than the other crops at the time of cutting, indicating that it could be less easily cured than alfalfa or timothy and clover mixed, and that less representative samples could be secured.

A variation of 5 per cent or more in the moisture content of the crops on different plats is deemed too great for accurate results; therefore, samples for making corrections of yields on the air-dry or water-free basis are necessary. When such samples are taken it has been found more desirable to weigh the product of each plat as soon as cut, especially if nitrogen determinations or complete analyses are to follow the determination of dry-matter content.

Alfalfa in Kansas, H. W. DOYLE ET AL. (Quart. Rpt. Kans. Bd. Agr., 35 (1916), No. 138, pp. 11-338, 447-472, figs. 288).—A detailed discussion of the production and marketing of alfalfa in Kansas.

[Alfalfa], L. F. Geaber and A. C. Johnson (Ann. Rpt. Wis. Agr. Expt. Assoc., 14 (1916), pp. 68-88, pls. 2).—According to the secretary's report at the fourth annual meeting of the Alfalfa Order of the Wisconsin Agricultural Experiment Association, out of 487 reports received from 796 farmers to whom alfalfa seed was distributed in the spring of 1914, 81 per cent reported good or fair success. Of the 19 per cent which reported poor stands or failures, the reasons given included lack of lime, lack of inoculation, poorly drained flat land, nurse crop too thick, early spring freezing and thawing, land of poor fertility, weeds and poor preparation of seed bed, crowded out by blue grass, drought after nurse crop was harvested, lack of snow covering, loose seed bed due to late spring plowing, and late fall cutting or pasturing.

Field experiments indicated that a 20-lb. rate of seeding gives the best results. There was no appreciable difference in winterkilling between southwestern- and northern-grown seed.

General notes on alfalfa production in Wisconsin are given, as well as statistics by A. C. Johnson concerning alfalfa in South Dakota.

Bermuda grass, S. M. Tracy (U. S. Dept. Agr., Farmers' Bul. 814 (1917), pp. 19, ftgs. 2).—The characteristics, adaptations, and uses of Bermuda grass in the South are discussed, including cultural directions and analyses.

Bermuda grass is said to compare favorably with timothy in feeding value, although its market value is usually less. Notes are given on the eradication of Bermuda grass by freezing the "roots," or by growing a winter smother crop of oats or rye followed by a summer crop of cowpeas or velvet beans.

Irrigation and manuring studies.—II, The effect of varying quantities of irrigation water and manure on the growth and yield of corn, F. S. Harris and D. W. Pittman (Utah Sta. Bul. 154 (1917), pp. 3-29, figs. 14).—In continuation of work previously noted (E. S. R., 31, p. 428), the results of irrigation and manuring experiments with corn are reported for the six-year period of 1911 to 1916, inclusive. In addition to the material discussed in the previous report, data on the composition of corn as affected by the irrigation and manurial treatments are presented for the first time. Detailed tabulated data regarding the crop are given for each treatment during the six years of the experiment.

The highest average yield of grain, 84.8 bu. per acre, was obtained with 20 in. of water, and the highest average yield of stover, 3.943 tons, with 30 in. With 40 in. of water the average yields were 79.2 bu. of grain and 3.817 tons of stover per acre, a decided decrease resulting in a waste of water and loss of time. The value of an acre-inch of water for applications of 5, 10, 20, 30, and 40 in. was \$1.90, \$0.87, \$0.69, \$0.42, and \$0.24, respectively, for each acre-inch.

Manure applied at the rate of 5 tons per acre showed an increased crop value of \$3.57 for each ton of manure. When applied at the rate of 15 tons per acre, the increased crop value was \$1.56 for each ton. These estimates do not take into account the cost of handling the increased crops produced by the different applications.

The influence of irrigation and manure on the yield of shelled grain, cobs, husks, stalks, leaves, and the percentage of each part is discussed in detail. The greatest yield of grain, cobs, and leaves was produced with 20 in. of water, while the yield of stalks was highest with 30 in., and of husks with 40 in. The yield of all parts was decidedly increased by manure, but not all in the same proportion. The amount of grain in proportion to the other plant parts was slightly decreased by manure, while the proportion of stalks was decidedly increased. Neither the size of the kernels nor the weight of a measured bushel of grain was greatly affected by the irrigation treatments. Manure, however, increased both the weight of the individual kernels and of a bushel of grain.

The height of the stalk of the plant increased with increased irrigation up to 30 in., but decreased with 40 in. of water. Unmanured corn was decidedly shorter than manured corn, but 5 tons of manure gave slightly higher stalks on the average than 15 tons. The longest ears were produced with no manure and with 30 in. of water. The length and width of the leaves increased with an increase of water up to 30 in., while manuring decidedly increased the leaf measurements.

Manuring greatly stimulated tillering, while the irrigation water was added too late to affect tillering. The number of leaves per stalk and the number of ears per plat increased with increased irrigation up to 20 in. and with manure. The average number of branches per tassel was affected by the same conditions that affected grain production.

The nitrogen content of the grain was reduced by the same irrigation treatments that increased crop yields, the percentage decreasing from 1.923 with no irrigation to 1.901 with 20 in. Manure, on the other hand, as a rule, increased the nitrogen percentage in the grain. In the total nitrogen per acre, however, the highest average production was secured with 20 in. of water, and amounted to 58.365 lbs.

The phosphorus content of the grain was affected irregularly by irrigation, but was increased by the manure. The calcium and magnesium content of the grain was not regularly influenced by the treatments.

From the results of the experiments, it was concluded that under similar conditions 20 acre-inches of water is the best amount for corn production, and that an annual application of 5 tons of manure per acre is sufficient for profitable corn production on Greenville soil.

Cotton production and distribution, 1915–16 (Bur. of the Census [U. S.], Cotton Prod. U. S., 1916, pp. 99, figs. 14).—Statistics are given on the supply and distribution of cotton in the United States, cotton production in the United States, consumption and stocks of cotton, imports and exports, the world's production of cotton, the world's consumption of cotton, cottonseed products, and cotton ginned by counties. Maps are given showing the cotton-producing area of the United States in 1915 and the center of production for the period of 1859 to 1914, the classification of States according to the quantity of cotton consumed in 1916, and the production of cotton in 1915 by counties for Alabama, Arkansas, Florida, Georgia, Louisiana, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee, and Texas.

Cotton in Brazil, W. W. Coelho de Souza (Lavoura: Bol. Soc. Nac. Agr. [Brazil], 20 (1916), No. 1-6, pp. 9-19).—A general discussion of the production of cotton in Brazil. A brief history of the crop in Brazil is given.

Cotton varieties in Brazil, E. C. GREEN (Classificação Summaria das Diversas Especies de Algodoeiros Cultivadas no Brasil. Rio de Janeiro: de Rodrigues & Co., 1916, pp. 14).—This is a brief summary and description of the cotton varieties grown in Brazil.

Third report on the improvement of indigo in Bihar, A. and Gabrielle L. C. Howard (Agr. Research Inst. Pusa Bul. 67 (1916), pp. 34, pl. 1; abs in Nature [London], 98 (1916), No. 2461, p. 335).—This is a supplementary report of work previously noted (E. S. R., 34, p. 36). The principles underlying the production of natural indigo are discussed, as well as seed production and improvement through selection and breeding.

The authors state that since the best color is obtained from those plants which secure their chief nitrogen supply from the root nodules good soil aeration is the most important phase of cultivation. Further notes are given on indigo wilt, together with recommendations for its prevention.

Peanut growing in the cotton belt, H. C. Thompson (Nat. Provisioner, 55 (1916), No. 19, pp. 26, 27, 35).—This is a popular article on the production of peanuts for oil in the cotton-producing sections of the South. The author states that with modern processes it is possible to obtain from 42 to 44 per cent of oil from shelled Spanish peanuts, 1 bu. of nuts weighing 30 lbs. yielding about 1 gal. of oil. The oil cake has about the same food value as cottonseed meal.

Home potato patches, C. S. KNIGHT (Nevada Sta. Bul. 87 (1917), pp. 8, figs. 2).—A brief, popular discussion of Irish potato production on small tracts in Nevada.

Potato growing in Wisconsin, J. G. Milward (Wisconsin Sta. Bul. 280 (1917), pp. 26, figs. 14).—Approved field practices and cultural methods employed in potato production in Wisconsin are discussed in detail and the standard varieties for the State briefly described.

Rice growing in New South Wales (Agr. Gaz. N. S. Wales, 27 (1916), No. 11, pp. 799, 800).—A brief report is made of the successful production of rice at the Yanco and Grafton experiment farms, New South Wales, in the season of 1915–16, with a variety known as Takasuka. At Yanco the crop was grown under irrigation. The results secured were deemed sufficient to justify further trials.

Soy beans, N. Schmitz (Maryland Sta. Bul. 201 (1917), pp. 131-158, figs. 6).— The adaptation of soy beans to Maryland conditions, their uses, and the field practices employed in their production both for seed and hay are discussed, extensive variety tests reported, and numerous varieties briefly described.

Thirty-six varieties have been tested for seed production for three years and more. Virginia has given the highest average yield, 20.06 bu., with Ebony second, with 19.84 bu. Cloud and Haberlandt have yielded 18.39 and 17.45 bu., respectively. The lowest average yield was secured from Mammoth, 10.12 bu. Of eight varieties tested for two or more years for hay production, the highest average yield was secured from Ebony, 4.29 tons, with an unnamed variety No. 3691 second, with 4.09 tons per acre. Virginia yielded 3.13 tons per acre. The lowest average yield, 2.58 tons, was secured from Edna.

Observations regarding inoculation indicate that on soils of low-to-medium fertility the best results can not be secured without inoculation, and even on those of high fertility inoculation is recommended. Soil inoculation is reported as much more satisfactory than the use of artificial cultures.

A 2-year test with 4 varieties for a comparison of the yield of seed when planted in 3.5-ft. rows and when drilled broadcast gave average yields of 13.38 and 16.41 bu. for the Edna and Virginia varieties, respectively, when planted in rows, as compared with yields of 19.1 and 16.9 bu., respectively, when drilled broadcast. Wilson and Ebony yielded 14.74 and 15.1 bu., respectively, when sown in rows, and 11.66 and 12.13 bu., respectively, when drilled broadcast.

Some recent investigations in sugar beet breeding, F. J. PRITCHARD (Bot. Gaz., 62 (1916), No. 6, pp. 425-465, figs. 51).—The studies reported in this paper have been briefly noted (E. S. R., 35, p. 442). The effect of environment on consecutive check and progeny rows is graphically illustrated in this paper, as it presents a number of phenomena having an important bearing on the final results of the investigations. The points studied included the relationships between a few commonly determined characters of the root and its yield of seed, the relationship between a root's yield of seed and the percentage of sugar in its progeny, the transmission of selected qualities of mother roots, selection of families, variability of progeny rows, effect of soil irregularities upon the variability of beet families, transmission of qualities exhibited by se-

lected families, deterioration from lack of selection, and the relationships between percentage of sugar, yield of sugar, and average root weight of sugar beet rows.

The observations reported indicate that although sugar beet improvement has been accomplished, continuous selection is not necessarily the basis upon which it has been attained. That the best roots transmit no better qualities than do the mediocre roots is shown by the tables and graphs submitted. The differences are mere fluctuations and have no definite influence upon improvement, although continuous selection applied to real differences as a possibility of improvement is still an open question. The real differences between sugar beet families are usually very slight and are greatly exceeded by their fluctuations. Both the best and the poorest families transmit average qualities, so that continuous selection is not an efficient means of improvement.

The isolation of mutants offers promise for improvement, but the number of individuals entering into these investigations was too small and the period of time over which the experiments extended (two generations) was too brief to determine the fact or the frequency of their appearance. If the mutation method is to be used for improvement, it is deemed essential that more efficient experimental methods be devised to reduce the effects of soil differences and make it possible to distinguish real differences more clearly. This can be accomplished by the more frequent use of check rows and by replications of the progeny rows. Whether the original stock or the new variety should be used as a source of material from which to isolate more valuable mutants can be determined only when it is known in which the mutants occur with the greater frequency.

Fundamentals of sugar beet culture under California conditions, R. L. Adams (California Sta. Circ. 165 (1917), pp. 22, figs. 4).—The field practices and cultural methods employed in sugar beet production in California are described and economic factors in the sugar beet industry briefly discussed.

The cost, value, and profit per acre for 10, 15, and 20 ton crops are estimated, the profits per acre being estimated at \$17.75, \$44.75, and \$67.25, respectively, indicating the advantage of good yields.

Russian sugar beet seed, T. G. Palmer (Sugar [Chicago], 18 (1916), No. 3, pp. 122, 123).—This is a general discussion of the sugar beet seed industry in Russia, with special reference to the extent of the industry in that country, the quality of Russian seed, and a comparison of the normal price of Russian seed with German and Austrian seed.

[Sugar cane varieties], J. Jeswiet (Arch. Suikerindus. Nederland. Indië, 24 (1916), Nos. 12, pp. 359-429; 17, pp. 625-636; 34, pp. 1321-1349, pls. 2, figs. 81; Meded. Proefstat. Java-Suikerindus., 6 (1916), Nos. 5, pp. 67-137; 8; 13, pp. 383-411, figs. 81).—This is a detailed botanical description, profusely illustrated, of the more important sugar cane varieties of the Dutch East Indies. A discussion of the morphology of the sugar cane, dealing with each portion of the plant in detail, descriptions of the two most important seed-producing varieties, and descriptions of the six varieties next in importance are included.

Notes on fallowing in sugar cane cultivation, F. Ledeboer (Arch. Suikerindus. Nederland. Indië, 24 (1916), No. 30, pp. 1157-1165; Meded. Proefstat. Java-Suikerindus., 6 (1916), No. 11, pp. 323-331).—This is a discussion of some rather limited experiments with fallowing in sugar cane cultivation extending over a three-year period. The results indicate that slightly higher yields were obtained from this practice, especially in dry seasons.

Lodging in sugar cane, and its prevention, H. F. K. Douglas (Arch. Suikerindus. Nederland. Indië, 24 (1916), Nos. 18, pp. 667-688, figs. 2; 21, pp.

821-825).—The author indicated that the younger a plant at the time of lodging the greater is the loss. The loss also varied directly with the degree of brittleness of the stem. Poor drainage aggravated lodging, while the removal of the dead leaves served to decrease the loss through lodging. Other causes which contribute to lodging are a lack of silicic acid in the stem; too frequent cultivation; overfertilization; shallow planting, whereby the cane becomes top-heavy; and severe wind and rain storms.

The prevention of lodging is said to be by "direct" and "indirect" methods. Direct methods are described as those which act without exerting any disturbing influence on the growth of the plant itself as deep planting, planting at different distances, and planting in such a way that the idividual plants afford each other support. The indirect methods include such practices as light fertilization, whereby the growth of the cane is less rapid and luxuriant; the application of phosphates to hasten maturity; the removal of dead leaves to permit of freer circulation of air and light; the strengthening of the stalk by the removal of some of the green leaves; and improved drainage, especially as the cane increases in height. Several authorities are quoted to some length in the course of the discussion.

Excerpts from correspondence between the author and other investigators on the value of potash fertilizers in regard to lodging are included. Opinion was found to be divided on this point.

Lodging in sugar cane, and its prevention, P. W. Houtman (Arch. Suiker-indus. Nederland. Indië, 24 (1916), No. 17, pp. 637-665, figs. 6).—The causes and effects of lodging in sugar cane are discussed, and suggestions made for its prevention.

The author outlines the causes of lodging as rank growth on fertile soil, too high nitrogen fertilization, the continuation of heavy rains through the vegetative period, wind and severe rain storms, and light, peaty soils affording insufficient support to the roots of the cane. Data and graphs are presented showing the degree and the effect on yield of lodging at different experimental centers and with different varieties.

While, as a rule, no attempt has been made to prevent lodging, there are certain definite measures that have proved beneficial. The author discusses these and presents data in support of his arguments. The methods noted are the tying up of the cane, less fertilization, earlier applications of the fertilizers used, wider plantings of the cane, and the use of varieties not addicted to lodging.

[Sugar cane] (Hawaii. Sugar Planters' Assoc., Rpt. Com. Cult. and Fert. Unirrig. Plantations, 1916, pp. 39, pl. 1, figs. 2).—The points taken up in this report include topping experiments, crop of 1916; stubble shaving; deterioration in the first mill juice; the handling of plant and ratoon fields and their green soiling; and fertilization by means of soil bacteria.

The relation of applied science to sugar production in Hawaii, H. P. AGER ET AL. (Hawaiian Sugar Planters' Assoc. Rpt. 1915, pp. 5-84, pl. 1, figs. 25).— A report compiled by the director of the Hawaiian Sugar Planters' Station at the request of the U. S. Department of Commerce, and with the cooperation of the station staff. The report includes an introduction and chapters on the experiment station work, and publications dealing with the application of scientific knowledge and discoveries to the sugar industry.

Sweet clover: Utilization, H. S. Coe (U. S. Dept. Agr., Farmers' Bul. 820 (1917), pp. 32, figs. 13).—The use of sweet clover for pasture, hay, silage, soiling, soil improvement, and as a honey plant is discussed in some detail.

Feeding tests noted from several sources indicate that this crop compares favorably with alfalfa and is an excellent feed for cattle and sheep. An acre of sweet clover will ordinarily support 20 to 30 shotes.

Instructions are given for the production of sweet clover hay and for the preservation of sweet clover as silage.

[Tobacco], D. Argerio (*Rev. Min. Indus. Uruguay*, 4 (1916), No. 20, pp. 27-58, figs. 12).—A general discussion of tobacco growing in Uruguay, with notes on the production of seedlings, transplanting, cultivation, harvesting, and yields.

Tobacco culture in Albania, A. BALDACCI (Bol. Tec. Coltiv. Tabacchi [Scafati], 15 (1916), No. 1-2, pp. 3-28).—A general discussion of tobacco culture in Albania and adjacent territory, especially as regards locally adapted varieties and general methods of cultivation.

Velvet beans: How to grow and use, C. B. WILLIAMS (North Carolina Sta. Circ. 35 (1917), pp. 4, fig. 1).—The production and use of velvet beans are briefly discussed, and varieties recommended for forage and seed production for different soil conditions.

Spring wheats, R. H. BIFFEN (Jour. Roy. Agr. Soc. England, 76 (1915), pp. 37-48, figs. 5).—The production of spring wheat in England and western Europe and the economic value of spring wheat as compared with the crops now in vogue are discussed, and a number of the more important spring wheat varieties available for use in these regions noted.

Red Fife, Burgoyne Fife, and Marquis are recommended as being superior to other varieties for early sowing. With Nursery and Red Marvel available for seeding late in February, Marquis and April Bearded can be safely sown as late as March.

A new hybrid yellow wheat, G. GAUDOT (Jour. Agr. Prat., n. ser., 28 (1915), No. 58, p. 581, fig. 1; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 12, pp. 1621, 1622).—A new wheat hybrid named Ceros, obtained by crossing Yellow Briquet with Autumn Victoria, is described. It has been grown ten years under varying conditions of soil and climate, and is reported to be perfectly hardy and remarkably rust-resistant.

On growing two white-straw crops in succession, E. J. Russell (Jour. Bd. Agr. [London], 22 (1915), No. 6, pp. 533-542, fig. 1; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 12, p. 1619).—
In an effort to determine to what extent fluctuations in yield are liable to occur in continuous wheat growing, the author compared the results obtained from the continuous wheat and barley plats of the Rothamsted Experimental Station.

It was found that the yields varied much more on the plats receiving artificial fertilizers than on those receiving farmyard manures. In a favorable season the yield increased to a greater extent by artificial fertilizers than by farmyard manure, but in unfavorable seasons the conditions were reversed. Wheat in rotation with clover gave higher yields and less variation than when grown continuously, so that continuous growing is deemed justifiable only where the cost of production is low or the prices high.

Two conditions essential to success are that the land be clean and that a suitable spring top-dressing be applied. The top-dressing will be determined by the needs of the second crop. Where the tilth is unsatisfactory soot or ammonium sulphate is recommended; otherwise, sodium nitrate.

Agriculture and the wheat supply, E. J. Russell (Nature [London], 98 (1916), No. 2458, pp. 269-271).—This is a general discussion of the ways and means of increasing the production of home grown wheat in England.

The wheats of Baluchistan, Khorassan, and the Kurram Valley, Garrielle L. C. Howard (Mem. Dept. Agr. India, Bot. Ser., 8 (1916), No. 1, pp. 88, pls. 2, flg. 1).—This is a botanical classification and detailed description of the wheats of Baluchistan, Khorassan, and the Kurram Valley, and a brief description of the barleys of Khorassan.

Third annual seed laboratory report, 1915-16, W. L. Oswald (Minnesota Sta. Bul. 165 (1917), pp. 12, figs. 4).—During the year 9,564 voluntary samples and 104 official inspection samples were tested for germination or purity, or both, and the results reported in tabular form. A 3-year summary of the seed-testing work is included in this report.

Seed impurities, A. H. COCKAYNE (Jour. Agr. [New Zeal.], 13 (1916), No. 3, pp. 208-212).—This is a list of 225 extraneous seeds found in commercial samples of seed on the New Zealand market, together with a key showing the relative frequency of occurrence and harmfulness of each.

Weeds on arable land and their suppression, Winifred E. Brenchley (Jour. Roy. Agr. Soc. England, 76 (1915), pp. 14-37, pl. 1, figs. 10).—This is a general discussion of weeds on cultivated land, including a glossary of 76 weeds mentioned in the paper.

Weed control with pulverized kainit, H. LINDEMAN (Tijdschr. Plantenziekten, 22 (1916), No. 5, pp. 107-121, pls. 10).—This is a general discussion of weed control with the application of finely ground kainit, including a comparison of kainit with ferrous sulphate in weed control.

# HORTICULTURE.

The persistence of lawn and other grasses as influenced especially by the effect of manures on the degree of soil acidity, B. L. Hartwell and S. C. Damon (Rhode Island Sta. Bul. 170 (1917), pp. 3-24, pls. 4).—This bulletin briefly reviews earlier work of the station on the subject (E. S. R., 20, p. 144), and reports in detail further experiments that have been in progress for a number of years. The effect on different kinds of grasses of changes in the degree of so-called soil acidity has received special attention. Soil acidity was modified not only by liming but by applying fertilizer combinations having acid, neutral, and alkaline reactions. Observations are also given on the effect on mixed herbage of variations in the amount of different nutrients, on the relative effectiveness of different sources of nitrogen used as top-dressings, and on the nature of the turf from different individual grasses and mixtures which were seeded in 1905.

The study as a whole has shown that with other conditions equal variations in the supply of individual nutrients may be expected to cause changes in the proportion of different grasses in a mixture. The most potent factor leading to the replacement of one grass by another appears to be variation in the degree of so-called soil acidity. The most common example of variation in herbage caused by modifications in the degree of acidity is the gradual replacement of timothy by redtop when manurial substances which are physiologically acid are applied and vice versa when alkaline substances are added. That the differences are not due merely to the physical and nutrient effects of the fertilizer was indicated in experiments where these effects were eliminated by the maintenance of optimum physical and nutrient conditions.

Having added at the time of seeding sufficient lime to create a soil reaction thought to be suited to the kind of grass adopted, any changes in reaction which are subsequently desired may be made by modifications in the annual top-dressing. The authors point out, however, that even when the specific

needs of a grass are known it is not always advisable to maintain these needs because the growth of certain undesirable plants may be promoted by the same conditions. For example, alkaline fertilizers suitable for promoting the best growth of blue grass are also favorable for the growth of dandelions and plantains. These weeds, as well as certain grasses like blue grass and also clover, are apparently checked by a degree of acidity which is not especially detrimental to the growth of bent and red fescue, which condition may be brought about by introducing sulphate of ammonia into the top-dressing in place of nitrate of soda.

The small vegetable garden (*U. S. Dept. Agr., Farmers' Bul. 818* (1917), pp. 44, ftgs. 22).—A popular treatise on vegetable gardening, discussing essentials of gardening, planning the small garden, choosing crops, aids to earliness (hotbed, seed box, and cold frame), tools, preparing the soil, planting vegetables in the open, gardener's planting table, cultivation, irrigation, protecting plants from diseases and pests, cultural suggestions for the commoner vegetables, vegetables for winter use, and fruits in the small garden.

Small fruit culture in California, A. H. Hendrickson (California Sta. Circ. 164 (1917), pp. 24, flgs. 13).—A popular treatise on the culture of bush fruits and strawberries, including a discussion of soils, methods of propagation, planting, cultivation, pruning, renewing the plantation, berries as intercrops, fertilizers, insects and diseases, harvesting, and varieties.

Spraying experiments in Nebraska, J. R. Cooper (Nebraska Sta. Research Bul. 10 (1917), pp. 5-98, figs. 26).—In continuation of previous work (E. S. R., 24, p. 758) this bulletin reports spraying experiments conducted on a large scale during the period 1913 to 1915 by the station in cooperation with the extension service of the university and growers in different parts of the State. The work was carried on to demonstrate known methods and evolve new methods of practice from a commercial as well as an experimental standpoint. The data secured each year in spraying for the codling moth, plum curculio, apple scab, and apple blotch are presented in detail and fully discussed. Tests of Bordeaux v. lime-sulphur and newer spray materials, together with data on the cost and efficiency of different methods of spraying, are also reported.

The results of the experiments as a whole show that the codling moth, plum curculio, apple scab, and apple blotch, together with incidental diseases such as rust and sooty blotch, may all be controlled by combining fungicides and insecticides and applying the first spray before the flowers open. The second spray should be given immediately after two-thirds to three-fourths of the petals have fallen, and the third spray immediately after the eggs from which the second brood of codling moth larvæ hatch are laid. A fourth spraying for the codling moth and apple scab may be necessary in certain seasons.

Practically no difference was found in the efficiency of Bordeaux and lime-sulphur in controlling fungus diseases, except in cases of apple blotch, where Bordeaux was more efficient but also more liable to injure the fruit when used early in the season. No way of eliminating Bordeaux injury has been found. The application of milk of lime following rains to trees which have been sprayed with Bordeaux does not lessen the injury to any appreciable extent. Bordeaux and lime-sulphur sprays may be interchanged in a schedule so as to form a maximum amount of control with a minimum amount of injury. Home-boiled lime-sulphur has been found as efficient a fungicide as the ordinary commercial product, but to avoid russeting the fruit care should be taken to screen out the coarse particles in the sludge, using only the clear liquid.

None of the new fungicides was found to be in any way superior to the two standard fungicides now in use. Bordeaux arsenate, Pyrox, and tuber tonic

were effective in controlling fungi but more dangerous to fruit and foliage and more expensive than Bordeaux. Soluble sulphur and atomic sulphur proved effective in controlling apple scab but did too much damage to fruit and foliage to warrant their use in their present form.

Practically no difference was found in any of the standard brands of arsenate of lead. Two lbs. of arsenate of lead paste or 1.25 lbs. of arsenate of lead powder have been found to be as efficient as larger quantities.

Spray applied with hollow stream nozzles was found fully as effective as when applied with the solid stream type. More spray injury and waste of material accompanies the use of the latter.

The results of the work of the last three seasons indicate that while it is sometimes possible to omit either the fungicide or the insecticide in the first spray, or to omit the first spray altogether without suffering serious loss, it is never safe to do so and is more hazardous to omit the fungicide than the insecticide. Clean culture was found to be of paramount importance in controlling the plum curculio and apple scab. Power machines are the most satisfactory where the orchard is large enough to warrant their use, though not necessarily more efficient than a good type of hand outfit when the latter is properly used.

Five years' investigations in apple thinning, E. C. Auchter (West Virginia Sta. Bul. 162 (1917), pp. 3-56, figs. 9).—This bulletin reports thinning experiments carried on by the station for the 5-year period 1912 to 1916. During this period 187 trees of different ages, growing under different environmental conditions and consisting of the varieties Rome, Baldwin, York Imperial, Delicious, and Ben Davis, were under test. For the most part the experiments were not conducted continuously on the same trees owing to the failure of the trees to set fruit in certain years, hence the results for each season are presented in detail. Owing to the lack of an apple crop in 1913 a thinning experiment with peaches was conducted and is here noted.

The results from the thinning experiments as a whole indicate that it does not pay to thin in years of light crop production if the trees are vigorous and growing in fertile soil. Where apple trees are bearing from a medium to a heavy crop of fruit the removal of a part of this fruit by thinning is a very profitable practice. In all cases where the trees had a good crop thinning increased the size and improved the color of the fruit, thus enhancing its market value. The results of the experiments indicate that thinning does not influence subsequent crops nor cause trees naturally biennial in bearing habit to bear a crop each year.

Winter varieties of apples may be thinned just after the June drop, since much of the fruit removed by too early thinning will drop off naturally at the time of the June drop and the remaining apples on the thinned trees may then be thinned too much. In the case of summer or early autumn varieties it is suggested that it will probably pay to delay thinning until the fruit is large enough to use and then several thinnings should be made as the fruits size up. In most cases the best results were obtained when the fruits were thinned 6 to 7 in. apart. In the case of old trees bearing good crops 9 to 10 in. apart gave slightly better results.

One year in one lot of 12 trees the thinned trees returned twice as much net per tree as did the unthinned trees. Another year the thinned trees gave at least a 75 per cent greater net return per tree. In some cases the increases were not so striking. The cost of thinning ranged from 8½ cts. to 43½ cts. per tree, depending on size of crop and tree. The author concludes that only a small part, if any, of the cost of thinning should be charged against the thinned trees, partly because the fruit thinned off would have to be removed

at picking time anyway and partly because it takes much longer and costs more in sorting to pick out the larger amount of unsalable culls from the unthinned trees.

The results of other investigators dealing with thinning apples are cited and a bibliography on the subject appended.

Inheritance of sex in Vitis rotundifolia, L. R. Detjen (North Carolina Sta. Tech. Bul. 12 (1917), pp. 5-43, figs. 37).—This is the fourth report on the station's investigations of V. rotundifolia (E. S. R., 31, p. 636), and deals specifically with the problems of transmission of sex. The important results secured in the work are summarized as follows:

"Hope, the first discovered hermaphrodite grapevine of the species V. rotundifolia, which bears upright stamens, is self-fertile. The self-fertility of the Hope vine is variable, and seems to depend on its inner constitution.

"Floral types in V. rotundifolia are transmitted to the progeny in definite ratios. Substituting S for staminate flowers, R for hermaphrodite flowers with reflexed stamens, and U for hermaphrodite flowers with upright stamens, we find that

 $R \times S = 1$  R: 1.06 S.  $R \times U = 1.07$  R: 1 U.

 $U \times U = S : R$  (ratios not determined).

"The Hope vine and some of its self-fertile progeny apparently will not cross with staminate vines. In *V. rotundifolia* the upright stamen in hermaphodite flowers is correlated with normal, viable pollen and self-ferility; the reflexed stamen in hermaphrodite flowers is always associated with defective pollen and self-fertility. The Hope vine and all of its seedlings, which bear upright stamens, appear and behave essentially like staminate vines except for the facts that the flowers usually contain well-developed pistils and that fruit is subsequently produced. The Hope vine probably is a staminate vine whose long suppressed pistils have suddenly been regenerated and have recovered the power to function. The prototype of our present-day rotundifolia vines probably was a true and functioning hermaphrodite."

Breeding southern grapes, L. R. Detjen (Jour. Heredity, 8 (1917), No. 6, pp. 252-258, figs. 4).—A popular discussion of this subject based upon the above noted investigation.

The use of commercial fertilizers in growing roses, F. W. Muncie (Illinois Sta. Bul. 196 (1917), pp. 511-564, figs. 37; abs. ed., pp. 4).—This bulletin describes in detail experiments with dried blood, acid phosphate, and potassium sulphate used in growing Killarney, Bride, and Richmond roses in the greenhouse during the period 1910 to 1913. These fertilizers were used both alone and in various combinations. Supplementary experiments were conducted during the period 1913 to 1915 to determine the value of acid phosphate with and without lime as a rose fertilizer. The results secured are presented in tabular form, also illustrated by a series of curves, and fully discussed.

Summarizing the experiments as a whole it was found that for the soil used at the station, a brown silt loam, fertilization is necessary to produce a maximum crop of roses. The benefit from fertilizing was in number of flowers produced and to a slight extent in the average stem length, though not in percentage of long-stemmed flowers. No measurable change in length of petals followed fertilization with acid phosphate, but applications of phosphatic fertilizer gave the most pronounced increase in the production of roses. Twenty lbs. of acid phosphate per 100 sq. ft. of bench space gave a profit of \$176 per 1,000 plants. Four times this quantity may be used without injury from overfeeding. The beneficial effect of acid phosphate was continuous throughout the year.

Dried blood in small amounts proved beneficial, but with amounts exceeding 8 lbs. per 100 sq. ft. of bench space there was a decrease in production with own-root and grafted Brides and grafted Killarneys. The effect of dried blood upon weekly production was found to be a decrease during the fall months, no difference during winter, and an increase in the spring.

No benefit was obtained from the use of potassium sulphate under the conditions of the experiment. Mixing ground limestone with the soil resulted in decreased production whether or not acid phosphate had been added. Hence ground limestone is not recommended for general use.

A definite relation was found to exist between the variation in hours of sunshine and the subsequent production of flowers. The experiment showed the desirability of planting grafted stock, since its larger production during the first year more than paid for the increase in initial cost.

Based on the experiments, the author recommends that the nitrogen content of rose soils be maintained by turning under green or farm manures before use. If lack of nitrogen is indicated by a lightening of the color of the foliage, applications of liquid manure, mulches of manure, or top-dressings of dried blood may be used, the last in applications not exceeding 5 lbs. per 100 sq. ft. of bench space, to be applied not oftener than six weeks apart. Nitrogenous fertilizers should be applied only during sunshiny weather and most generously during periods of heavy production. Generous quantities of acid phosphate should be added to the soil. It may be applied in the field at the rate of 4 to 8 tons per acre and in the bench soil at the rate of 40 to 80 lbs. per 100 cu. ft. of soil. Neither lime nor limestone should be mixed with the soil. If needed for sweetening the soil and for preventing the growth of algæ a top-dressing of finely-ground limestone at the rate of 10 lbs. per 100 sq. ft. of bench space may be applied.

### FORESTRY.

Proceedings of the Southern Forestry Congress, held in Asheville, N. C., July 11 to 15, 1916 (*Proc. South. Forestry Cong., 1916, pp. 187*).—A report of numerous papers, addresses, and discussions at this meeting of the Southern Forestry Congress. Problems dealing with forest protection, organization, legislation, and management in their relation to the protection and development of southern forest industries received special consideration.

Tree growth and climate in the United States, K. W. Woodward (Jour. Forestry, 15 (1917), No. 5, pp. 521-531).—A summary of the available information with regard to forest yields in the United States and a discussion of the relation of these yields to climate and soil. Fifteen forest types are differentiated with special reference to climatic and soil characteristics.

Laws of tall-tree growth investigated mathematically, R. D. BOHANNAN (Jour. Forestry, 15 (1917), No. 5, pp. 532-551).—In this article the author undertakes to prove a number of formulas and laws relating to height growth in forest trees, presents age-height-diameter tables for various American trees, and gives notes on the measurements of the different species.

The problem of making volume tables for use on the National Forests, T. T. Munger (Jour. Forestry, 15 (1917), No. 5, pp. 574-586).—In this paper the author calls attention briefly to the part that the Branch of Research of the Forest Service of the U. S. Department of Agriculture should take in the preparation of volume tables, sketches some of the questions that arise in their preparation, and suggests some of the principles that should guide the work.

Site determination, classification, and application, R. Watson (Jour. Forestry, 15 (1917), No. 5, pp. 552-563, fig. 1).—The purpose of this article is to

indicate a possible standard method of site determination and of site classification. In order to test the validity of the methods advocated they are applied in a practical manner to a timber survey.

Volume of western yellow pine logs from an actual mill tally, S. Berry (Jour. Forestry, 15 (1917), No. 5, pp. 615-618).—A mill tally of western yellow and Jeffrey pine is here described with special reference to the application of the data secured in estimating the quality of standing timber in a given area.

The Swiss method of regulating the cut in practice, C. H. Guise (Jour. Forestry, 15 (1917), No. 5, pp. 564-573).—The author used the Swiss method of regulating timber cut in the preparation of working plans for two forest tracts. The data secured are here given and discussed. It is believed that the results secured warrant the further use of the Swiss method in regulating the cut in mixed selection forests.

Effect of depth of covering seed upon the germination and quality of stock, S. B. Show (Jour. Forestry, 15 (1917), No. 5, pp. 619-623).—The results are given of a series of experiments conducted at the Feather River Experiment Station of the Forest Service of the U. S. Department of Agriculture on the effect of depth of covering seed upon germination and quality of stock. The species included in the experiment were western yellow pine, Jeffrey pine, sugar pine, Douglas fir, white fir, and bigtree. With the exception of sugar pine, the conclusions regarding all the species are based on spring sowing only. The results secured for each species are presented in tabular form and discussed.

A study of reforested chestnut cut-over land, E. C. M. RICHARDS (Jour. Forestry, 15 (1917), No. 5, pp. 609-614).—Experiments on the reforestation of chestnut cut-over land with pine transplants, here described, lead the author to conclude that pine will establish itself readily on cut-over land, but that chestnut and other hardwood sprouts should be cleaned out not later than three years after planting the pine and this should be repeated every three to five years until the pine attains a height of 12 to 15 ft. and overtops neighboring hardwoods.

In these plantings, which were made in New Jersey and Connecticut, chestnut blight did not kill the sprouts soon enough to prevent injury to the pine.

Forest succession in the central Rocky Mountains, C. G. Bates (Jour. Forestry, 15 (1917), No. 5, pp. 587-592).—In this paper, which is based upon general observations over a number of years in the mountainous territory of Colorado and Wyoming, the author discusses different tree associations and successions with the view of indicating the practical importance to the forester of taking into account the systematic development of vegetation by definite stages.

The woodlot, C. A. Scott (Kansas Sta. Circ. 58 (1917), pp. 37, figs. 24).—A treatise on woodlot management with special reference to conditions in Kansas. A list is given of desirable trees for Kansas woodlots, including data on the uses of each kind of wood and estimated yield per acre in lumber and other products. A table is given showing an itemized account of the cost of growing a 20-acre catalpa plantation and the returns received from it. The total expense per acre for growing and harvesting the plantation, which was about 16 years old at the time of cutting, was \$109.83. The net proceeds per acre was \$152.17, equivalent to an annual net income of \$9.31 per acre.

Some timely suggestions for the owners of woodlots in New England, F. H. Mosher and G. E. Clement (U. S. Dept. Agr., Bur. Ent., 1917, pp. 8).—Based on observations conducted by the Bureau of Entomology over a number of years some 75 species of native and naturalized trees are here grouped into

the following classes: Species that are favored food of gipsy moth larvæ in all their stages, species that are favored food for gipsy moth larvæ after the earlier larva stages, species that are not particularly favored but upon which a small proportion of the gipsy moth larvæ may develop, and species that are unfavored food for gipsy moth larvæ. The suggestions herein given constitute, in a general way, a guide for the thinning of the above classes of trees in New England woodlots, with reference both to the utilization of the wood and the protection of the trees from gipsy moth attacks.

Tree planting needed in Texas, J. H. Foster and H. B. Krause (Bul. Agr. and Mech. Col. Tex., 3. ser., 3 (1917), No. 1, pp. 32, figs. 12).—A popular treatise on tree planting for windbreaks, shelter belts, fence posts, and fuel, as well as planting in streets, city parks, and school and home grounds.

Report of committee on forestry, L. A. Thurston et al. (*Proc. Hawaii*. Sugar Planters' Assoc., 36 (1916), pp. 333-368).—A report of tree planting and other forest activities of the Hawaiian Sugar Planters' Association, including a report by C. S. Judd upon the present status of forestry in Hawaii.

Douglas fir shipbuilding, H. B. OAKLEAF ([Portland, Oreg.], 1916, pp. 9, figs. 2).—A general account of the utilization of Douglas fir in shipbuilding.

Brazilian woods: Their utilization for the manufacture of wood pulp (Jour. Forestry, 15 (1917), No. 5, pp. 624-627).—This is a reprint of an article from the London Times, giving analyses of a number of woods suitable for wood pulp, together with information relative to the volume and distribution of these woods, conditions, and estimated cost of exploitation, etc.

The purchase of pulpwood.—Some suggestions, C. P. Winslow and R. Thelen ([Madison, Wis.], 1916, pp. 8, figs. 2).—A paper read before the Technical Association of the Pulp and Paper Industry at a meeting held at Columbia University, New York City, on September 28, 1916.

#### DISEASES OF PLANTS.

Fungus and bacterial diseases, W. Nowell (West Indian Bul., 16 (1916), No. 1, pp. 17-25, 28, 29).—This is a descriptive and tabular account of the distribution and severity, during 1915, of fungus and bacterial diseases, including root disease (Marasmius sacchari), rind fungus (Melanconium sacchari), red rot (Colletotrichum falcatum), pineapple disease (Thielaviopsis paradoxa), and Cephalosporium sacchari of sugar cane; anthracnose (Colletotrichum gossupii), West Indian leaf mildew, a bacterial boll disease, angular leaf spot, black arm, and other diseases of cotton; root disease (Rosellinia pepo), canker (Phytophthora faberi), black pod rot (P. faberi), brown pod rot (Lasiodiplodia theobroma, dieback and stem diseases (L. theobroma), pink disease (Corticium salmonicolor), horse-hair blight (Marasmius sarmentosus) and other diseases of cacao; black root disease (Rosellinia spp.), red root disease (Sphærostilbe sp.), pink disease (C. salmonicolor), and an unidentified root or collar disease of limes and citrus trees, and other diseases of limes; root disease (M. sacchari) and white rust (Albugo (Cystopus) sp.) of sweet potatoes; bud rot, root disease, and leaf diseases (Pestalozzia palmarum) of coconuts; brown rust (Puccinia maydis), smut (Ustilago zea), and root disease of Indian corn; rust (P. purpurea) and smut (Sphacelotheca sorghi) of sorghum and Guinea corn; root disease (Sclerotium sp.), leaf rust (Uredo arachidis), and leaf spot (Cercospora personata) of peanuts; bacterial rot and damping-off of onions; and tuber and wilt diseases of yams.

The wet year, 1915, was highly favorable to fungi parasitic on scale insects. Phanerogamic parasites noted include Cuecuta americana, Cassytha filiformis,

Dendropemon sp., and Phorandendron sp. Some other plant troubles having different causes are noted.

Annual report of the mycologist for the year 1913-14, W. J. DOWSON (Dept. Agr. Brit. East Africa Ann. Rpt. 1913-14, pp. 118-121).—A disease of sisal is thought to be due to climatic conditions.

The coffee leaf disease due to *Hemileia vastatrix* was treated successfully with Bordeaux mixture. Formalin in weak solution was found protective but it retarded germination.

Diseases identified included the coffee leaf disease (H. vastatrix), rusts of wheat (Puccinia graminis, P. glumarum, and P. triticina), barley (P. simplex), maize (P. sorghi), peach (P. pruni-spinosæ), fig (Uredo fici), carnation (Uromuces caryophyllinus), bean (U. appendiculatus), mildew of rose (Sphærotheca pannosa), tobacco (Erysiphe communis), cucumber and marrow (E. cichoracearum), and grape anthracnose (Glæosporium ampelophagum). Diseases still unidentified include the bud rot of Cocos nucifera, a blackening of the stems of Manihot glaziovii, a root disease of young Juniperus procera, a heart rot of the same plant due to a Fomes, and a leaf disease attacking citrus trees, other than limes.

Annual report of the mycologist for the year ending March 31, 1915, W. J. Dowson (Dept. Agr. Brit. East Africa Ann. Rpt. 1914-15, pp. 94-107).— In this report, which is particularly concerned with administrative and other matters, it is stated that coffee is regularly attacked by Hemileia vastatrix, but that the disease is not very virulent and is not considered a dangerous pest if properly handled. The effects on this parasite of seasonal and weather conditions, and of various fungicides and combinations thereof, are detailed.

Withertip of citrus trees is under investigation, the only organism found in connection with the specimens examined being Colletotrichum glæosporioides. Dead leaves on the ground are thought to aid in spreading the disease...

Rose leaf mildew (Spharotheca pannosa) is reported as again very prevalent on susceptible varieties. Copper sprays control the disease but scorch the foliage of certain varieties.

Bud rot disease of the coconut palm, or a root rot disease, or both together, caused mortality among the older trees. Drainage and manuring are considered the only practicable remedies. Of the several bacteria isolated from diseased material, one closely resembled *Bacillus coli communis*.

A list is given of parasitic fungi recorded during 1914-15, in connection with associated plant diseases.

Some problems connected with the treatment of fungus diseases by spraying, E. S. Salmon and J. V. Eyre (Gard. Chron., 3. ser., 60 (1916), No. 1559, pp. 229, 230).—In this paper the authors, discussing some of the results of experimentation and practice in the use of fungicides against plant diseases, state that to make this work thoroughly efficient its problems must receive detailed attention from three sides, relating to the fungus, the host plant, and the chemical substance of the fungicide. These phases are briefly discussed.

Control of root knot by calcium cyanamid and other means, J. R. WATSON (Florida Sta. But. 136 (1917), pp. 145-160, fig. 1).—A description is given of plant and greenhouse experiments with calcium cyanamid for the control of root knot on various plants.

As a result of his investigations, the author recommends the use of calcium cyanamid thoroughly mixed with the soil, after which the beds are to be well irrigated. This treatment, it is said, will so greatly reduce the number of nematodes as to make the growing of susceptible crops profitable. The amount of cyanamid required will vary from one thousand to several thousand pounds

per acre, according to the depth and nature of the infested soil. On account of the burning effect of the cyanamid, an interval of one to several weeks should intervene between the treatment of the soil and the planting of the seed. The cost of the treatment is such that its use is recommended only on seed beds and truck lands under intensive cultivation, but as cyanamid is an important source of nitrogen its use as a fertilizer should be considered in connection with nematode control.

Rosellinia root diseases in the Lesser Antilles, W. Nowell (West Indian Bul., 16 (1916), No. 1, pp. 31-71, pls. 7, figs. 2).—Rosellinia, several species of which cause root disease in numerous temperate and tropical countries, occurs in this relation in the Lesser Antilles, Guadeloupe, Dominica, Martinique, St. Lucia, St. Vincent, and Grenada, but not on the other islands of the group which have drier climates. Though the range of hosts as regards classification is also very wide, the plants most affected in this region are cacao, coffee, limes, and arrowroot. Cacao is attacked usually by R. pepo (possibly in certain localities by another species not yet identified), which spreads from roots of dead or dying shade trees. Limes and coffee plants are attacked by both R. pepo and R. bunodes.

Infested trees may be killed by the progressive investment of the roots (spreading from roots of other trees) or by the destruction of the bark around the collar. The fungus penetrates quickly both bark and wood, conidia being readily formed where the mycelium is exposed, and perithecia occurring later.

Preventive measures include periodical inspection, aeration, insulation, disinfection, liming, flaming, and removal of infected wood.

Observations on a new disease in cotton, M. L. PATEL (Poona Agr. Col. Mag., 8 (1916), No. 1, pp. 45-48).—A disease, affecting most of the native varieties of cotton in certain districts, is described. The leaves on some branches turn pinkish yellow just before blooming, the number of blooms is reduced, and the young bolls produced remain small and dry up quickly.

The trouble, locally termed sterility, was more severe in 1915-16 than in 1914-15. It varies somewhat in severity with season, soil, and variety, but it does not appear to be due primarily to diminished water supply or to lack of nutrient material. An observed shortness of the taproot is thought to be a result, not a cause, of the disease. Belated attacks are less severe. Mites are observed to be more common on affected than on other portions of the plant. No disease organism has been isolated. The bolls open poorly on affected plants. The seeds are lighter in affected cotton, but the lint is proportionately still lighter, as shown by a lowered ginning percentage; also the lint is said to be more brittle in diseased cotton.

Removal of all affected branches appears to prevent the disease so far as the individual plant is concerned.

Studies on clubroot of cruciferous plants, C. Chupp (New York Cornell Sta. Bul. 387 (1917), pp. 419-452, figs. 16).—The author has made a study of the clubroot of cruciferous plants due to Plasmodiophora brassicæ in an attempt to determine the part played by swarm spores in the dissemination of the fungus, spore germination, the manner in which the pathogene enters the host, the distribution of the organism throughout the tissues of the root, the formation and size of the spores, and the reputed relation of bacteria to the normal development of the myxomycete.

As a result of his investigations he has found that neither the motility of swarm spores nor the action of winds is an important factor in the dissemination of the parasite. Each spore is said to produce one swarm spore which, if not supplied with a host, develops no further. Penetration of the host takes

place through the wall of the root hair while the organism is in a uninucleate stage. The root hair at once shows hypertrophy. The amœba increases in size as it passes rootward, and finally, by direct cell-wall penetration as well as by the division of the host cells, the pathogene is distributed throughout the cortical tissue. Aside from *P. brassicæ* there is said to be often present another organism which causes no hypertrophy and which is probably *Olpidium brassicæ*.

In the experiments to determine the relation of bacteria to *P. brassicæ*, as claimed by Pinoy (E. S. R., 14, p. 946), all the results obtained indicate that the bacteria do not enter the host as soon as the slime mold does, but follow only after there has been a rupture of the epidermis. Consequently the bacteria can be of no vital importance in the nutrition of the parasite.

Bitter pit investigation.—The experimental results in their relation to bitter pit and a general summary of the investigation, D. McAlpine (Rpt. Bitter Pit Invest. [Aust.], 4 (1914-15), pp. 178, pls. 41, figs. 2).—This is the author's fourth report on this work (E. S. R., 33, p. 852), and sums up the results of the study carried on by him for four years under appropriations by the Commonwealth and State governments of Australia.

The causation and prevention of the disease by direct measures received the greater portion of attention, as breeding experiments were precluded by the time limitation imposed. Extended investigations failed to connect the disease with any parasitic organism. It is claimed to be due to a disturbance of the normal functions of the plant itself. In some apple varieties, the majority of the trees showed a tendency to the pitting habit, and some individual trees showed bitter pit to the extent of 60 or 80 per cent of their crop. Abundance of material was obtained from the six States included in the investigation.

It is held that success against bitter pit depends entirely upon the ability of orchardists to control the conditions in the individual trees, and the ability of shippers to control conditions, chiefly temperature, during transit. Apparently, the factors operative in the production of bitter pit include every phase in the life of the tree, from the nursery to the marketed fruit. The experimental work is reported in considerable detail and the practical applications of the results obtained are pointed out. It appears that apples apparently faultless can be shown, by means of the X-ray, to be affected, the honeycombed appearance of a pitted apple contrasting sharply with the solid flesh of a healthy fruit. Apparently the disease begins on the tree and continues to develop under certain unfavorable storage or shipping conditions.

Biochemical researches were conducted by Rothera, Jackson, and Kincaid. The absence of development of bitter pit in apples kept at 32° F. is thought to be simply the usual phenomenon of arrest due to slowing up of all vital activities at that temperature, as nothing indicates a permanent influence of such temperature on this disease. It appears that the pitting of applies is determined before they are picked and before their starch is converted into sugar, though laboratory experiments indicate some possible influence of treatment (as handling) after picking. Further work needs to be done in this connection.

Other studies were conducted in cooperation at various points by different persons, who are named. Susceptible and nonsusceptible varieties were compared as regards the composition of the fruit and the nature of the leaf, since it appeared evident that retardation in the leaves would result in increased transportation of water to the fruits. Yates, which is nearly immune, appears to be more nearly allied to the wild crab apple than is the susceptible variety,

Cleopatra. It is stated that the tendency to bitter pit is more or less inherent in the constitution of the cultivated apple, no matter where it is grown.

Bitter pit is considered a functional disorder, the vascular system, or conducting tissue, being largely concerned. The cultivated apple has evidently lost, in large degree, the hardy nature of its wild ancestors, its vascular system having failed to keep pace with the requirements laid upon it during the development of such various desirable qualities as size. A softening of the fiber, a delicacy of constitution, and a feebleness in the power of rapid transportation of water, etc., have necessitated measures to counteract the inadequate conduction in the tissues.

Studies on the relation of laterals to bitter pit were inconclusive. Ringing and fracturing the branches was tried, and it was found that checking the flow of sap in September resulted in a diminution of pitting, and for the last two seasons there was none at all. The results from constricting the branches with wires were inconclusive, as were those from ringing pear trees. The fall of the leaves was not affected.

Observations described seem to indicate that apples should not be kept in an ordinary storeroom where the air is overdry. In case of apples on the tree, the temperature of the atmosphere and its humidity appear to modify the effects of the sun's rays. Slightly less pit developed in apples grown in sheltered situations, transpiration being reduced when the drying effects of wind are moderated.

A study of bitter pit in its relation to weather shows that it is not strong transpiration in dry air or weak transpiration on dry soil that induces bitter pit, but that it is the amount of transpiration relatively to the water supply that is the important factor. The general evidence indicates that the nature of the scion, and not that of the stock, is the deciding factor in varietal susceptibility. As regards situation, the least suitable is one having a southerly exposure, and the most favorable is one having a northeasterly aspect, well sheltered from west and south winds.

Of all orchard operations, pruning appears to have the most direct effect upon the development of bitter pit, which is least prevalent when there is a good average crop with fruit, generally of normal size, well distributed over the tree. The pruning operation should be carried on continuously from the time of planting through the bearing period. The objects to be aimed at are not only increased vigor and luxuriant growth, but also the distribution of the fruits on the tree so that each receives its due share of sun, shade, air, and nourishment.

While many facts and suggestions are variously presented in the body and conclusion of this report, it is thought that the ultimate solution of the problem must be obtained from breeding experiments looking to the production of otherwise desirable varieties which do not develop bitter pit.

A brief bibliography is appended.

Xylaria root rot of apple, F. A. Wolf and R. O. Cromwell (U. S. Dept. Agr., Jour. Agr. Research, 9 (1917), No. 8, pp. 269-276, pl. 1, figs. 3).—In continuation of a preliminary report on the black root rot of apple (E. S. R., 36, p. 147), the authors give an account of further investigations carried on at the North Carolina Experiment Station on this disease. This trouble is found to be widely distributed in North Carolina, and it is believed to be the same disease which has been reported in Virginia and Pennsylvania.

There are said to be no above ground symptoms by which this disease may be distinguished from other apple root rots. The roots, however, are said to be characteristically covered with black fungus incrustations from whose margins radiate minute black rhizemorphs. Isolations have constantly yielded a

form whose conidial fructifications and stromatic arms indicate its relationship to *Xylaria* spp., and from a study of the perithecial material, the fungus is considered morphologically quite like *X. hypoxylon*. The pathogenicity of the organism has been repeatedly established by inoculation with pure cultures into the roots of living apple trees. The ascigerous stage of a species of Xylaria has been found on diseased apple roots, but this has not yet been connected with the conidial stage developed in artificial cultures.

[Brown rot of plum and apple] (Gard. Chron., 3. ser., 60 (1916), No. 1561, p. 251, figs. 2).—Brown rot, due to Sclerotinia (Monilia) fructigena, is reported as having been severe early in the season of 1916 on apples, and later on plums. This disease is said to have been increasingly common during recent years, supposedly due to the exceptional prevalence of moisture in winter and spring.

The best plan for protection is considered to be that of drenching the trees with lime-sulphur of winter strength, or Bordeaux mixture, just before the buds begin to open and afterwards cutting off and burning all diseased material. Turning the ground during the winter is also recommended.

Further studies of the orange rusts of Rubus in the United States, L. O. Kunkel (Bul. Torrey Bot. Club, 43 (1916), No. 11, pp. 559-569, figs. 5).—According to the author, there are two forms of the orange rust of blackberries in the United States. One is the exoma stage of Gymnoconia interstitialis and the other a short-cycle rust with a life history similar to the Endophyllums. The two rusts are morphologically alike in their exoma stage, though quite different in their life histories. The short-cycled Cxoma nitens seems to be more widely spread in the United States than is G. interstitialis, and to the first species is attributed most of the injury of orange rust on blackberries and raspberries.

Note on a Botrytis disease of fig trees, W. B. BRIERLEY (Roy. Bot. Gard. Kew, Bul. Misc. Inform., No. 9 (1916), pp. 225-229, pls. 2).—An account is given of the development of B. cinerea when tested in pure culture, and when inoculated into twigs, in which it causes a dieback, and into fruit, which becomes mummified, any leaves developing the following season being dwarfed and primitive in form.

The "band" disease of betel-nut palms in the Konkan, V. G. GOKHBLE, R. S. KASARGODE, and S. L. AJREKAR (Poona Agr. Col. Mag., 8 (1916), No. 1, pp. 49-53).—A disease of betel-nut palms, known locally as "band" and causing decline, barrenness, and finally death of the trees, has been known in portions of the Ratnagiri district for more than 30 years, reducing the yield materially. There is no indication that the trouble is communicable. Soil conditions, which are thought to be largely or wholly responsible for the development of the disease, include the presence of soil exhaustion, bad drainage, acidity, and toxic substances. Spacing and intergrowths may also be factors. Progress as regards remedial measures is at present hampered by lack of knowledge regarding the physiology of the betel palm.

An epidemic of rust on mint, A. H. Chivers (Mycologia, 9 (1917), No. 1, pp. 41, 42).—In gardens at Hanover, N. H., early in the summer of 1915, an epidemic of rust (Puccinia menthæ) on mint developed suddenly and increased rapidly after a period of heavy and continuous rainfall, this being the first outbreak of the rust in this locality so far as known. Though nothing was done in the way of control or prevention, the disease did not reappear in 1916. It is thought that this disease, which is capable of destroying the foliage of mint during a wet season, may become inactive on return of normal seasons.

[Lophodermium pinastri and Phacidium infestans on pine], T. LAGERBERG (Statens Skogsförs. Anst. [Sweden], Flygbl. 5 (1915), pp. 10, flgs. 6).—This is a brief discussion of L. pinastri, which causes a pine needle cast, and P. infestans, which is said to kill out young pines in the nursery.

The pine blister disease (Amer. Forestry, 22 (1916), No. 276, pp. 748-750, figs. 2).—It is stated that the white pine blister, or canker, has made steady progress in the portions of New England from which it has been previously reported, and that what are thought to be the areas of new infection have been discovered recently, so that the situation is constantly becoming more serious.

Recent study of pod disease and canker in Hevea, A. A. L. RUTGERS (Meded. Adv. Alg. Ver. Rubberplanters Oostkust Sumatra, No. 5 (1916), pp. 63-66).—The author, having carried on for some time a study of Hevea canker (E. S. R., 32, p. 242), which is claimed to be caused by Phytophthora faberi, states that slightly infected trees recovered in nearly every case, and trees severely infected in a number of cases. This form of the fungus is thought to be identical with that causing a disease of cacao and other plants. Infection experiments with Hevea fruits succeeded, causing a rot thereof in several instances.

A root disease of plantation rubber in Malaya due to Poria hypolaterita, W. N. C. Belgrave (Agr. Bul. Fed. Malay States, 4 (1916), No. 11, pp. 347-350).—This is a preliminary report on investigations continued since 1915, and still in progress, on a wet foot rot of mature rubber trees in Malaya, which is described as due to P. hypolaterita.

The disease is spread by root contact, its progress being slow and insidious, the trees yielding latex until they are very far gone. The fungus is suspected to be too common in jungle lands to justify the use of isolation trenches except, possibly, to isolate the larger-infected areas. This may be done with deep drains, the trees being then tapped until they die, which may require at least five years.

Some suggestions on the control of mistletoe in the National forests of the Northwest, J. R. Weir (Forestry Quart., 14 (1916), No. 4, pp. 567-577).—This article, while relating mainly to forestry measures and methods, notes also the fact that mistletoe brooms, and eventually the uninfected parts of the tree, cease to produce seed, which may be a serious matter in view of the trying conditions related to reproduction and survival of forest growths. It is stated also that the false mistletoes (Razoumofskya) are of much greater importance in the western than in the eastern portions of the United States, practically every western conifer being attacked by at least one of these parasites, which may be inconspicuous but usually show a greater degree of parasitism than do the Phoradendrons.

The author reports briefly on a study of the more minute details of the anatomy of the sinkers and horizontal root system of the parasite, stating that the phloëm of the host is found to be, in some species, in direct union with the absorbing cells of the parasite. The weakening of heavily infested young trees, and other facts noted, are considered as proof of a heavy drain on the host by the parasite. The fact that if a seed of one of these species falls on a plant other than an accustomed host it will exhaust its energy in producing a long hypocotyl without penetrating the substratum is considered proof of a special adaptation of the parasite to particular types of cell structure or chemical constitution of the hosts. This fact may become important in connection with the planting of mixed forests. Mistletoe attacks hosts of all ages, and trees attacked when young are apt to be otherwise diseased.

# ENTOMOLOGY.

Recognition among insects, N. E. McIndoo (Anat. Rec., 11 (1917), No. 6, pp. 517, 518).—The experimental results here reported deal only with the odors emitted by honeybees.

Proceedings of the Entomological Society of British Columbia (Proc. Ent. Soc. Brit. Columbia, Econ. Ser., No. 9 (1916), pp. 49-88, figs. 17).—The more important papers of practical or popular interest to fruit growers and farmers presented at the fifteenth annual meeting of the society, held at Victoria, British Columbia, in 1916, are here given, namely, Notes on the Wood Tick (Dermacentor venustus), by J. W. Cockle (pp. 53-57); The Cottony Maple Scale (Pulvinaria innumerabilis), by T. Wilson (pp. 57-59); The Pea Weevil in British Columbia, by R. C. Treherne (pp. 59, 60); Entomology in the Public School, by J. A. Hamilton (pp. 60-62); The Forest-insect Problem in Stanley Park, by R. N. Chrystal (pp. 63-66); Some Orchard Insects of Economic Importance in British Columbia, by R. C. Treherne (pp. 66-83); Superheating as a Control Method for Insects Which Infest Stored Products, by A. Gibson (pp. 83, 84); and Control of Cabbage Aphis by Parasites in Western Canada, by E. H. Strickland (pp. 84-88).

Seventh annual report of the State entomologist, C. P. GILLETTE and G. M. List (Off. State Ent. Colo. Circ. 19 (1916), pp. 43).—This is the usual annual report, dealing particularly with the inspection work of the year.

[Parasite work in Maine], J. N. Summers (Agr. of Maine, 1915, pp. 116-127, pls. 4).—The first of the two papers, here presented, reports (pp. 116-119) upon the work of 1915 at the Maine Parasite Laboratory. The second (pp. 120-127) consists of a discussion of the parasites of the gipsy and brown-tail moths in Maine, including a brief history of those thus far introduced into the State, namely, Anastatus bifasciatus, Apanteles lacteicolor, Meteorus versicolor, Compsilura concinnata, and Monodontomerus wreus, and the predator Calosoma sycophanta.

Report of the economic zoologist, H. A. Surface (Ann. Rpt. Penn. Dept. Agr., 21 (1915), pp. 174-205, pls. 4).—This report consists largely of details relating to the work of the year, particularly as relate to orchard, nursery, and apiary inspection, etc.

The results of studies of the life history and habits of the red leaf or cherry leaf beetle (*Galerucella cavicollis*), which was recently found in Pennsylvania, are briefly reported. This beetle is said to have been very destructive in several counties in the northern and central portions of the State, feeding upon the foliage of cherry, peach, apple, pear, and some other trees, shrubs, and plants.

A detailed account of this leaf beetle by Cushman and Isely has been noted (E. S. R., 35, p. 260).

[Insect pests], H. A. Surface (Bi-Mo. Zool. Bul. Penn. Dept. Agr., 6 (1916), Nos. 1, pp. 58, pls. 5, figs. 19; 2, pp. 59-118, pls. 5, figs. 10; 3, pp. 119-149, figs. 6; 4, pp. 23).—These papers deal, respectively, with (1) pests of truck and farm crops and live stock; (2) pests of trees; (3) pests of the household, etc.; and. (4) bee diseases in Pennsylvania.

[Report of the] division of entomology, E. E. Scholl (Ann. Rpt. Comr. Agr. Tex., 9 (1916), pp. 10-27).—This report deals with the occurrence of some of the more important insect pests of the year in Texas and measures for their control.

[Report of entomological work], H. P. AGEE (Hawaii. Sugar Planters' Assoc., Rpt. Expt. Sta. Com., 1916, pp. 4-10).—This reports upon the progress of work for the year ended September 30, 1916.

Several additional egg parasites of the leaf-hopper were introduced, one belonging to the genus Paranagrus and two to the genus Ootetrastichus. The Anomala beetle is slowly extending its damage into the cane fields at the outskirts of the infested district. Mention is made of several predators and parasites of this pest which are being introduced.

Insect pests [in the West Indies during 1915], H. A. BALLOU (West Indian Bul. 16 (1916), No. 1, pp. 3-16, 26, 27).—This is a record of the occurrence of the more important insect pests during 1915.

[Insect pests in St. Vincent] (Imp. Dept. Agr. West Indies, Rpt. Agr. Dept. St. Vincent, 1915-16, pp. 7-9, 11-13, 15-17, 18, 19, 20-28, 31-34).—This paper deals with the occurrence of the more important insect pests of cotton, cassava, corn, Lima beans, etc., and includes a report of a special study of the egg parasite Trichogramma minuta, a report of the work connected with insect and fungus pests and their control, and an account of the native food plants and feeding habits of the cotton stainer. Much of the data has been previously noted from other sources (E. S. R., 35, p. 355; 36, pp. 153, 253, 654).

[Insects of economic importance in South America] (An. Zool. Aplicada, 1 (1914), No. 1, pp. 17-22, 25-27, 29, 30, 37-41, 44-79, figs. 28).—The papers here presented, relating to insects in Chile, include the following: Simulidæ of Northern Chile, by F. Knab (E. S. R., 35, p. 258); A New Scolytid in Chile, Phlæotribus porteri, by C. Bruch; Description of a New Prionomitus in Chile, by J. Brèthes; Insecticide Formulas Recommended for the Destruction of Coccids and Other Insects, by E. Molina; Résumé of Work in Peru on Phlebotomus verrucarum and Its Agency in the Transmission of Verruga, by C. H. T. Townsend (E. S. R., 35, p. 258); and Contribution to the Economic Entomology of Chile, by C. E. Porter.

[Insects of economic importance in South America] (An. Zool. Aplicada, 3 (1916) No. 1, pp. 6-29, 31-54, figs. 9).—The papers here presented include the following: Discovery and Interpretation of the Stages in the Asexual Cycle of the Organism of Verruga Peruviana, by C. H. T. Townsend; Description of a New Genus and a New Species of Ortalidæ in Chile, namely, Eupterocalla opazoi, by J. Brèthes; Description of a New Chilean Dipteran (Agromyza gayi), by C. E. Porter; The Codling Moth, by A. Paillot; Description of Two Chilean Hymenoptera, namely, Pteroptrix australis n. sp., and Heterobelyta chilensis n. g. and n. sp., by J. Brèthes; Phlebotomus papataci, the Transmittor of Three Days' Fever, by R. Morales; Lepidoptera of Economic Importance in La Rioja, Argentina, by E. Giacomelli; Introduction of Diaspis pentagona and the Control of This Pest in Argentina, by A. Gallardo; and A Contribution to the Economic Entomology of Chile, by C. E. Porter.

[Insects and insect control in Germany] (Mitt. K. Biol. Anst. Land u. Forstw., No. 16 (1916), pp. 15-58, figs. 5).—Several papers relating to insects and their control are here presented, namely, Tests of Insecticides, by Schwartz (pp. 15, 16); Observations on Insect Pests (pp. 16-19) and On the Knowledge of Red Spider Mites (pp. 19-25), by Zacher; Contribution to the Knowledge of the Migratory Plant Lice in Germany, by Börner and Blunck (pp. 25-42); The Appearance of Winged Forms of Plant Lice (pp. 42, 43) and The Blood-dissolving Fluids in the Body of Plant Lice and Their Behavior Toward Plant Juices (pp. 43-49), by Börner; and Bee Diseases, by Maassen (pp. 51-58).

Annual report of the entomological laboratory for the year ended March 31, 1915, T. J. Anderson (Dept. Agr. Brit. East Africa Ann. Rpt. 1914-15, pp. 38-54).—This consists largely of a preliminary annotated list of 129 economic insects of British East Africa.

Some reasons for spraying citrus trees in Florida, W. W. Yothers (Fla. Grower, 15 (1917), Nos. 10, pp. 5, 6; 11, pp. 7, 8; 12, pp. 9, 10).—The advan-

tages resulting from spraying for the control of insect pests and mites as a supplement to the benefits resulting from natural enemies are pointed out.

The cat-tail rush, Typha latifolia, as a summer host of injurious insects, W. M. Davidson (Mo. Bul. Com. Hort. Cal., 6 (1917), No. 2, pp. 64, 65, fig. 1).—
This rush, which serves as a summer host for a number of important pests, is abundant in California along water courses, in ponds and marshes, and in irrigation ditches. It frequently thrives in close proximity to orchards and remains green throughout the long, dry summers while the grasses and weeds in great part begin to die off in the late spring.

The plum aphis (Hyalopterus arundinis) is perhaps the chief insect pest which feeds upon it, spring migrants arriving from plums and apricots at the end of April and continuing to arrive until the end of July. The reddish-brown plum aphis (Rhopalosiphum nympheæ), which occurs on plums of both European and Asiatic origin, uses the cat-tail as summer host along with other water plants, including Alisma, Nymphea, Potamogeton, etc. Ordinarily predators control this aphid quite effectively, while the smaller colonies of the mealy aphis more frequently escape. The grain aphis colonizes T. latifolia during the summer and fall, winged forms arriving in May and June, and another such generation departing in the late autumn. Aphis avenæ, the oat aphis, is another grass species that may be found on it, often in large colonies, during the summer and fall. A small, black aphis, probably A. gossypii, also occurs in small numbers on this host plant during the summer and fall months, migrating forms appearing at the end of October. Red spider mites of the genus Tetranychus feed on it, sometimes in abundance, during the summer months.

Hackberry insects and their control, F. B. Paddock (*Proc. Texas Farmers' Cong.*, 18 (1915), pp. 103-106).—This is a brief summary of the insect enemies of the hackberry and means for their control.

Contribution to a study of the toxins of spiders, R. Lévy (Ann. Sci. Nat. Zool., 10. ser., 1 (1916), No. 4-6, pp. 161-399, figs. 6).—This work reviews the literature and reports upon investigations conducted.

The genera and species of Mallophaga, L. Harrison (Parasitology, 9 (1916), No. 1, pp. 156).—This paper has been prepared primarily with the view of placing a complete list of the systematic nomenclature of the group in the hands of students of Mallophaga, no attempt having been made to bring the host list up to date. The subject matter is divided into eight parts under the headings of general introduction; list of species of Mallophaga included in the genera Pediculus, Ricinus, and Nirmus; list of generic and subgeneric names, valid and invalid, used for Mallophaga; scheme of classification; list of species and subspecies, valid and invalid, of Mallophaga; bibliography; list of new names introduced in this publication; and index to genera.

Field notes on Virginia Orthoptera, H. Fox (Proc. U. S. Nat. Museum, 52 (1917), pp. 199-234).

Fourth campaign against locusts (Schistocerca peregrina) in Algeria by means of Coccobacillus acridiorum, Béguet (Bul. Soc. Path. Exot., 9 (1916), No. 9, pp. 679-682).—A continuation of the work previously reported (E. S. R., 36, p. 356).

The distribution of virulent cultures of *C. acridiorum* on the food has always started an epidemic in the bands of *S. peregrina*. Such epizootics, however, have never brought about their complete disappearance.

The fungus on cacao thrips, W. Nowell (Agr. News [Barbados], 15 (1916), No. 383, p. 430).—The fungus which occurs as a white mold on the body of Heliothrips rubrocinctus in St. Vincent has been identified by R. Thaxter as Sporotrichum globuliferum.

The cost of spraying in the control of the pear thrips in British Columbia, A. E. CAMERON, R. C. TREHERNE, and E. W. WHITE (Agr. Gaz. Canada, 4 (1917), No. 1, pp. 18-16).—These data are based upon spraying work in the spring of 1916 with hand and power outfits in which some 138 acres, comprising 11,569 bearing fruit trees of mixed varieties, were treated.

The green apple bug in Nova Scotia, W. H. BRITTAIN (Nova Scotia Dept. Agr. Bul. 8 (1917), pp. 56, pls. 8, figs. 6).—This bulletin relates to a form previously described by Knight as Lygus communis novascotiensis (E. S. R., 36, p. 550), one of the most serious pests of apples and pears in Nova Scotia. It contains much data based upon work during 1916 in addition to that for 1915 noted from another source (E. S. R., 36, p. 457).

"The young begin to emerge several days before the blossoms open, the maximum emergence coinciding with the period of full bloom of the Bartlett pear, or just as the Gravenstein blossoms begin to open. The nymphal stage is of about 32 days duration. The adults begin to die off within a couple of weeks after reaching maturity, but are found in diminishing numbers throughout the summer and early autumn. The winter is passed in the egg state, beneath the bark of the twigs.

"The young bugs or nymphs are very active and elusive in their habits, and as they increase in size, exhibit an increased tendency to drop to the ground. Leaves, stems, blossoms, and fruit are freely attacked, but blossoms and fruit are preferred. They are occasionally predactious in habit, and though apparently fragile, can exist for sveral days without food and are able to make their way over the ground for comparatively long distances. The adults are active insects and strong fliers, though under ordinary conditions they do not appear to wander far from the orchard in which they have developed. In feeding, the adults prefer a diet of fruit, and that of pears is most attractive to them when they first reach maturity."

The spiny citrus white fly.—A potential pest of citrus trees, J. C. Hutson (Agr. News [Barbados], 16 (1917), No. 384, pp. 10, 11).—An account is here given of Aleurocanthus woylumi, a species recently described by Quaintance and Baker (E. S. R., 35, p. 552), which is already attracting considerable attention in Jamaica, the Bahama Islands, and Cuba.

The author reports observations of the past in the Guantanamo Valley, Cuba, where it was discovered in August. 1915, attacking a few citrus trees in a grove of about 8.000. During the course of an inspection made in the early months of 1916, it was found that this aleyrodid had spread so rapidly in the infested grove that practically all the trees were infested. It was prevalent in the neighboring town of Guantanamo, and an inspection of the main portion of the valley showed that practically all the citrus trees within a well-defined area of the valley and foothills were more or less infested by it. In addition to attacking oranges and grapefruit, it occurs on other species of citrus, mango, coffee, guava, sapodilla, star-apple, etc.

The spiny citrus white fly and means for its control in Cuba (Sec. Agr. Com. y Trab., Com. Sanid. Veg. Cuba. Circ. 1 [1916], pp. 6).—This gives a brief description of Aleurocanthus woglumi and methods of combating it.

On the supposed varieties of Chry.comphalus dictyospermi, E. Malenotti (Redia, 12 (1916), No. 1, pp. 109-123, figs. 6; abs. in Rev. Appl. Ent., Ser. A, 4 (1916), No. 11, p. 468).—The author takes the view that there are no true varieties of C. dictyospermi, a scale which infests at least 80 different species of plants belonging to about 25 quite dissimilar families in both tropical and temperate climates.

The codling moth and its control in the Western Province, F. W. Petter (Union So. Africa Dept. Agr., Sci. Bul. 9 (1916), pp. 48, figs. 7).—A report of a detailed study of the codling moth commenced in the summer of 1915.

Statistics on the production of silk in France and elsewhere (Statistique de la Production de la Soie en France et a l'Etranger. Lyon: Syndicat de l'Union des Marchands de Soie de Lyon, 1917, pp. 68).—This, the usual annual summary (E. S. R., 36, p. 655), covers the year 1915.

The meadow foxtail midge, A. H. Cockayne (Jour. Agr. [New Zeal.], 18 (1916), No. 6, pp. 459-466, figs. 5).—Oligotropus alopecuri, originally thought to be a variety of the wheat midge, is probably distributed wherever meadow foxtail is cultivated. During 1915 the crop was virtually ruined in the Manawatu district, one of the two principal seed-producing localities in New Zealand. In many cases 70 per cent of the seed was destroyed and the output rendered quite unsalable. In 1916 the infestation was even worse in this district and no seed was harvested.

Anopheline mosquitoes.—Their distribution and infection under field conditions, M. B. MITZMAIN (*Pub. Health Rpts.* [U. S.], 32 (1917), No. 15, pp. 536–540).—This is a report of investigations, conducted in continuation of those previously noted (E. S. R., 36, p. 757), that were undertaken primarily for the purpose of ascertaining the relative distribution of anophelines under field conditions and included also an effort to determine for a particular locality (Talladega Springs, Ala.) the seasonal period at which parasitism of mosquitoes could no longer be demonstrated.

In the above-mentioned region the maximum parasite index among 200 persons was found to be 18.6 per cent. With a view to determining whether conditions exist in nature in the presence of which this mosquito may be of epidemiological significance, a total of 1,377 specimens of two species of Anopheles (A. quadrimaculatus and A. punctipennis) were collected during the period from September 18 to November 15, 1916. "It is indicated that in the three sources of direct human influence, namely, inside dwellings, under dwellings, and in privies, the last produced the greatest number of specimens of A. punctipennis. This species comprised less than one-third (30 per cent) of the catch in houses, while under dwellings 62 per cent of the mosquitoes collected proved to be A. punctipennis."

The preponderant numbers of A. punctipennis infesting houses were usually found in an engorged state resting under the flooring of dwellings. Although A. punctipennis rarely bites while inside a dwelling, it is found to attack persons seated on the porch or gallery of the house, after which these mosquitoes seek rest, presumably under the house in preference to the interior. In one instance infection was noted in a specimen of A. quadrimaculatus examined on November 15.

Is mosquito or man the winter carrier of malaria organisms? M. B. MITZMAIN (Pub. Health Serv. U. S. Bul. 84 (1916), pp. 32, pls. 8).—This is a report of investigations made in a territory comprising 15 plantations in Bolivar and Washington Counties, Miss.

It is concluded after an examination of 2,122 dissected anophelines collected in this region that hibernating anophelines did not harbor parasites of malaria. In the investigation of man as the responsible winter carrier, 1,184 persons residing in the section above mentioned were examined for malarial parasites and 492 infections were identified microscopically, i. e., nearly one-fourth of the human carriers harbored gametocytes. Of these, 317 cases were of the subtertian type, 8 were mixed infections, and the remainder were of the simple tertian type, with the exception of one quartan case.

"The incrimination of man as the sole winter carrier is emphasized by the fact that three malaria-infected *Anopheles quadrimaculatus* were found in the homes of these gametocyte carriers during May 15 to May 26, previous to which time, 1,180 specimens of Anopheles from this source were found to be negative."

See also previous notes (E. S. R., 36, pp. 255, 757).

Experimental studies with muscicides and other fly-destroying agencies, E. B. Phelps and A. F. Stevenson (*Pub. Health Serv. U. S., Hyg. Lab. Bul.* 108 (1917), pp. 37, figs. 2).—A detailed report of experimental studies which have been substantially noted from another source (E. S. R., 37, p. 53).

The limitations of kerosene as a larvicide, with some observations on the cutaneous respiration of mosquito larvæ, J. W. S. Macfie (Bul. Ent. Research, 7 (1917), No. 3, pp. 277-295, fig. 1).—It is pointed out that many localities are ill-suited for the application of kerosene, that many surfaces of water can not be efficiently oiled, and that by no means all the species of mosquitoes that bite man breed close to houses.

Experiments made to determine the action of kerosene as a larvicide, the survival of submerged larvæ, etc., are reported.

Observations on the distribution of warble flies in Ohio, D. C. Mote (Ohio Jour. Sci., 17 (1917), No. 5, pp. 169-176, flgs. 2).—This is a report of studies conducted in Ohio largely during 1914 and 1916, in which it is shown that Hypoderma bovis is the most abundant species, comprising nearly 83.5 per cent of 628 grubs and 15 adults collected in 32 counties. See also work noted in Ohio Station Bulletin 278 (E. S. R., 32, p. 796).

The poplar and willow borer (Cryptorhynchus lapathi), R. Matheson (New York Cornell Sta. Bul. 388 (1917), pp. 457-483, pl. 1, figs. 18).—The poplar and willow borer is a European beetle, first discovered in this country in 1882, which has become so abundant in many eastern nurseries during the past 10 to 20 years that in many cases the nurserymen have almost abandoned the raising of Carolina and other species of poplars. It is also a serious enemy of practically all species of willows and where the beetle is abundant the damage done is extensive, this being especially true of all varieties of ornamental willows, while the production of basket willows is greatly reduced and in many cases stopped by its work. In addition to poplars and willows it has been recorded as attacking several species of alders and two species of birch. At the present time it is known to occur from Maine west to Ontario and North Dakota and south to the District of Columbia.

In New York State the adults begin to appear during the latter part of July, are abundant in August, and have been found present on poplar trees as late as October 7. Shortly after emerging from the pupal cells they begin to feed, selecting young, tender shoots. The bark is punctured by the beak, a round hole being formed down to the cambium layer, on which the beetles largely feed. They are such voracious feeders that when abundant the young 1-year-old shoots may be so completely, riddled that they shrivel and die. Punctures in old bark are for the deposition of eggs, and these always appear some weeks after the beetles have been feeding. While their wings are perfect and apparently suitable for flying the beetles have never been observed in flight or attempting to fly, and in the nursery it is not uncommon to find one block badly infested, whereas a block somewhat distant may be only slightly injured.

The eggs are placed in corky parts of the bark on branches or parts of the tree more than a year old, from 1 to 3 or 4 eggs being deposited in a cavity. Oviposition continues from early August until October, but the number of eggs

deposited by a single female has not been determined; from 18 to 25 days are required for their incubation, the first of which out-of-doors were observed to hatch on October 2.

The young larva feeds on the tender tissues of the plant and soon reaches the soft cambium layer. Externally the beginning of feeding can be easily recognized by the blackish wet frass that fills the outer part of the egg cavity. Feeding continues until cold weather and commences the following spring as soon as the weather becomes sufficiently warm.

Pupation begins in the last few days of June and continues throughout July, the pupal period varying from 10 to 18 days, those formed early in July requiring only 10 days while those late in July require the full 18 days. Individuals maturing early in the season usually remain in the pupal cells for two or three weeks before emerging, a general emergence of adults occurring the latter part of July.

It is pointed out that the observations of European workers do not entirely agree with those made in New York State, thus indicating that the life history and habits of this insect are complex and vary greatly.

Extensive experiments were carried out on large blocks of trees in nurseries in which varying strengths of miscible oils, emulsions, etc., were applied both in the fall and in the spring. Such work carried on during 1913–14, 1914–15, and 1915–16 has shown that carbolineum avenarius, when applied to the trunk to a sufficient height, gives nearly absolute control. A high-grade creosote which has been tried in a limited way has also given a perfect control. Carbolineum is not injurious to the hands and can best be applied by dipping cotton waste into the material, then rubbing carefully up and down the trunk of the tree to a height of 4 or 5 ft. It is pointed out that great care should be exercised to see that the base of the tree is well treated and all parts of the trunk well covered.

Carbolineum gives the bark of the trees a deep-brown color but in no way affects their vigor. While this brownish coloration gradually becomes reduced during the summer, the treated trees can be recognized easily for at least three years after treatment. In the experimental plats treated in 1913–14 trees were not attacked during 1914 and 1915 and only a single larva was found in them during 1916, indicating that they are not readily selected by the females for ovlposition, provided untreated trees are available.

In nurseries the carbolineum should be applied by hand during the latter part of March and the first week in April. This can be most advantageously done just after the trees are pruned. A careful account of the entire cost of treatment in one nursery showed it to average not more than 0.2 ct. per tree.

Studies of this beetle by Schoene have been noted (E. S. R., 18, p. 957). A 3-page bibliography is included.

Experimental evidence that bark borers are able to kill healthy fir trees, A. Welander (Skogsvårdsför. Tidskr., No. 6-7 (1916), pp. 520-526, figs. 3; abs. in Rev. Appl. Ent., Ser. A, 4 (1916), No. 12, pp. 507, 508).—Experiments reported indicate that Ips typographus is able to kill perfectly healthy trees.

The bean beetle (Epilachna corrupta), D. E. MERRILL (New Mexico Sta. Bul. 106 (1917), pp. 3-30, pls. 4, flg. 1).—This is a report of studies of E. corrupta, a leaf-eating coccinellid or lady beetle which is the most injurious insect attacking the bean in New Mexico. Although its yearly damage is estimated in various localities at from 5 to 100 per cent, the author considers an average of 10 per cent to be a conservative estimate. The injury is caused by both the adult beetles and the larvæ eating outright or skeletonizing the leaves.

The larvæ feed on the under surface of the leaves in colonies when they are young, but scatter later. When at all numerous they eat off the lower epider-

mis and all the green substance of the central layers of the leaf, whereas the adults eat holes here and there entirely through the leaves, rarely destroying the whole leaf. The young pods may be attacked, holes being scraped in their sides, or an occasional flower eaten.

The species was first described from Mexico in 1851 and occurs in Arizona, Colorado, New Mexico, Texas, and Utah. There are two broods of the bean beetle each year in the southern part of New Mexico, where the life-history studies were conducted. The hibernated adults oviposit from June 15 to August 1. The first-brood larvæ were found from June 19 to August 23; the first-brood pupæ from July 5 to August 28; and first-brood adults from July 10 throughout the season, of which some may hibernate. The second-brood eggs are found from July 16 to the end of the season; second-brood larvæ from July 20 to the end of the season; second-brood adults from August 5 to the end of the season; and second-brood adults from August 10 on, in which stage they hibernate.

The eggs are deposited in clusters, as a rule not contiguously, on the underside of the leaves, 46 being the average number of eggs per cluster for 39 clusters counted. The maximum egg production among 8 females observed was 754 in 14 clusters, the minimum was 93 eggs in two clusters, and the average 291 eggs per female. The average period of incubation was 5.8 days, with 4 days as the minimum and 9 days the maximum. The larval period (4 instars) required an average of 16.8 days for the first brood, with a maximum of 21 and a minimum of 15 days; for the second brood an average of 15.7 days, with a maximum of 19 and a minimum of 15 days. The pupal period averaged 4.7 days for either brood, with 5 days as a maximum in each, while the minimum for the first brood was 3 days and for the second 4 days. The average total time from egg to adult was 25.9 days for the first brood and 25.4 days for the second brood; the shortest time was 22 and the longest 28 days.

It is pointed out that injury may be reduced to a minimum by cooperation in the use of preventive measures of control, including time of planting, rotation, clearing of fields, etc. Attention is called to the fact that a gain of from one to two weeks in planting is of considerable importance at the crucial point of the infestation. But few natural enemies have been observed. Preliminary experiments with arsenicals and blackleaf 40, briefly reported, indicate that lead arsenate may be of value.

The 1916 tests of sulphur-arsenical dusts against the strawberry weevil, T. J. Headlee (New Jersey Stas. Circ. 65 (1917), pp. 3-7, fig. 1).—The remarkably efficient results obtained from the use of mixtures of arsenate of lead and sulphur for the strawberry weevil during 1915 (E. S. R., 35, p. 364) led to more extensive tests in Atlantic. Cumberland, and Burlington Counties during 1916.

The results obtained on a representative farm in Atlantic County on which careful records were kept, presented in tabular form, show net returns at the rate of more than \$100 per acre or a maximum increase of 200 per cent. The mixture of one part of lead arsenate to five parts of sulphur, while a little less effective than the 1:1 mixture, was much the better from the standpoint of net returns. It is shown that neither sulphur by itself nor arsenate of lead used alone is anywhere nearly so effective as the two combined. This is thought to be due to the fact that while neither substance alone flows freely through a powder gun a mixture of the two does so readily, and thus permits the application of a much more even and complete coating. Since careful examinations again failed to reveal any considerable number of dead beetles on treated plats, it is concluded that the mixtures act as repellents.

The year's experience with machinery for making applications is said to have been largely unsatisfactory. Mention is made of a satisfactory hand sifter which has been devised by T. Rizzotte, consisting of a common wire nose muzzle

covered with one thickness of copper mosquito netting, 15 wires to the inch, the open edges of which are drawn up and tied to the rim. By using a 3-ft, hickory sapling bent as a bow and the ends fastened to the opposite sides of the rim a good coating can be applied to rows varying in width from 18 in, to 3 ft, by twirling the apparatus over the row as the operator walks along.

From 80 to 90 lbs. of the mixture are required per acre for each treatment. Ordinarily two applications are sufficient, the first when weevil-feeding on the bud begins and the second about one week later or as soon as the coating given by the first treatment has lost its completeness. Every bud should be kept dusty.

Further trial of sulphur-arsenate of lead dust against the strawberry weevil, T. J. HEADLEE (Jour. Econ. Ent., 10 (1917), No. 2, pp. 287-290, fig. 1).—Noted above.

Method of cockchafer control used in Germany, K. ESCHERICH (Ztschr. Angew. Ent., 3 (1916), No. 1, pp. 134-156; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 6, pp. 910-912).—Control experiments with the cockchafer (Melolontha vulgaris and M. hippocastani) in the Bienwald in the Upper Palatinate are reported.

Descriptions of various chalcidoid Hymenoptera with observations, [III], A. A. Girault (Entomologist, 50 (1917), No. 645, pp. 36-38).—This third (not fourth) paper (E. S. R., 36, p. 555) with descriptions of three parasites new to science, includes Podagrion mantidiphagum reared from an egg mass of a mantid in the British West Indies, and Paraleptomastrix notatus reared from Pseudococcus bakeri on the grape at Fresno, Cal.

Notes on chalcid flies, chiefly from California, A. A. GIRAULT (Jour. Ent. and Zool., 9 (1917), No. 1, pp. 8-12).—Descriptions of seven new species are given.

Notes on coccid-infesting Chalcidoidea, II, J. WATERSTON (Bul. Ent. Research, 7 (1917), No. 3, pp. 231-257, figs. 9).—This second paper (E. S. R., 37, p. 162) presents descriptions of seven chalcidoid parasites of Coccide from the Gold Coast that are new to science.

Annual reports of the State bee inspector for the years 1915 and 1916, F. C. Pellett (Ann. Rpt. State Bee Insp. Iowa, 4 (1915), pp. 72, pls. 2, figs. 9; 5 (1916), pp. 103, figs. 11).—These reports of the work for the years 1915 and 1916 include the proceedings of the fourth and fifth annual conventions of the Iowa State Beekeepers' Association.

The question of denatured sugar for the feeding of honeybees, E. ÎA. Zarin (*Trudy Selsk. Khoz. Bakt. Lab., 5 (1915), pt. 3, pp. 371-390*).—This discussion includes a report upon the experimental feeding of bees with sugar denatured with various substances. In experiments with paprika and methyl violet, coal tar and animal oils, the latter was found the better, as a moderate addition of the animal oil can not influence harmfully the color or taste of the honey.

Beauveria peteloti n. sp., a polymorphous Isaria parasite of Hymenoptera in tropical America, F. Vincens (Bul. Soc. Bot. France, 62 (1915), No. 4-6, pp. 132-144, pls. 4).—This fungus is parasitic on two wasps (Polybia chrysothorax and Polystes canadensis) and an undetermined bee.

## FOODS-HUMAN NUTRITION.

The effect of high temperatures on the nutritive value of foods, A. G. Hogan (Jour. Biol. Chem., 30 (1917), No. 1, pp. 115-123, figs. 9).—Earlier work by the author (E. S. R., 36, p. 158) indicated that young laboratory animals (rats) were unable to grow upon a diet which had been subjected to high

temperatures. Accordingly, further experiments with rats were made on the nutritive properties of heated foods. In some instances the ration consisted of corn and in others of corn and egg white, a salt mixture being added to the diet to compensate for the mineral deficiencies of maize. The heating process was continued for six hours at 30 lbs. pressure.

It was found that heating the egg white had little or no effect, but in every case where corn was heated the diet was inadequate in some respect and the animals were unable to maintain body weight. It was suggested that some factor other than that of food accessories was altered, and to investigate this point a comparatively pure protein, egg white, was heated in an autoclave for six hours at 30 lbs. pressure. This was dried and combined with protein-free milk, butter, starch, and agar in such proportions that the protein formed about 9 per cent of the ration. "This diet did not permit maximum growth, and possibly these rats grew somewhat more slowly than other animals receiving a similar ration in which the protein had not been heated. Evidently, however, the nutritive value of the protein had not been seriously impaired."

Similar experiments with casein in the ration instead of egg white were carried out, the casein being heated for two hours, but at different pressures, namely, 15, 30, and 45 lbs., while unheated casein was given to one lot of control animals. In these rations protein formed approximately 12 per cent. "In all cases animals of the same sex grew at approximately the same rate, indicating that the nutritive value of the casein had not been materially lowered by the high temperature. . . .

"The heating process described in this paper does not materially lower the nutritional value of protein. It is suggested that one or more of the so-called food 'accessories' may be injured by high temperatures."

Bread making, MAY C. McDonald (N. Dak. Agr. Col. Ext. Bul. 7 (1917), pp. 16, figs. 4).—This bulletin discusses the ingredients used in bread making and describes the processes of mixing, rising, and baking. Recipes are given for making different kinds of breads.

The proteins of the peanut, Arachis hypogea, C. O. Johns and D. B. Jones (*Proc. Nat. Acad. Sci., 3 (1917)*, No. 5, pp. 365-369).—Two globulins, arachin and conarachin, together with a trace of albumin, have been isolated by the authors from the peanut. The greatest difference between the two globulins is in the percentage of sulphur, conarachin containing nearly three times as much as arachin. Both equivalents are characterized by a high percentage of basic nitrogen.

The article also discusses briefly the nutritive value of the peanut and especially the question of supplementing wheat and corn with peanut meals.

[Bacteriological examination of milk, ice, oysters, ice cream, and catsup], W. R. Stokes (Ann. Rpt. Bd. Health Md., 1913, pp. 166-170).—The results are reported of the examination of several samples of these products.

[Report of the State Food and Drug Commissioner and the Bureau of Chemistry of the Maryland State Board of Health], C. Caspari, Jr., and W. B. D. Penniman (Ann. Rpt. Bd. Health Md., 1913, pp. 179-193).—This report covers the work done in the inspection and examination of foods during the year ended December 31, 1913, data being given regarding a number of samples of miscellaneous food products and the inspection of a large number of establishments where food is prepared and sold.

[Pure food topics and drug inspection], E. F. LADD and ALMA K. JOHNSON (North Dakota Sta. Spec. Bul., 4 (1917), No. 12, pp. 331-338, 341-346).—This bulletin contains a brief article on The So-called "Vitamins" or "Food Accessories" and Their Importance in the Nutrition of Animals, by F. W. Christensen, and reports the results of the examination of a number of samples of drugs.

Food and efficiency, Martha Tracy (N. Y. Med. Jour., 104 (1916), Nos. 16, pp. 748, 749; 18, pp. 851-853; 20, pp. 953, 954; 22, pp. 1054-1056; 24, pp. 1149-1151; 26, pp. 1245-1247; 105 (1917), No. 2, pp. 75-78).—This is a summary and digest of recent experimental data on various topics of food and nutrition.

Food, fuel for the human engine, E. L. FISK (New York: Life Extension Institute, Inc., 1917, pp. 32, fig. 1).—A popular bulletin on the selection and use of food. Much of the material given is based on a three-weeks' dietary test with 12 young men, in which the cost of food was kept within the limit of 25 cts. per day. The menus and recipes used in this test are given and a modification is suggested of the menus for a family including young children.

Practical suggestions regarding food values and the proper selection of a nutritious and economical diet, A. M. G. Soule (Bul. [Maine] Dept. Agr., 16 (1917), No. 1, pp. 36, figs. 2).—This publication contains data regarding the classification of foods and the composition of different food materials and suggestions for the economical selection of the different foods.

Diet lists, compiled by H. S. Carter (*Philadelphia: W. B. Saunders Co., 1913, pp. VII+129*).—This is a compilation of different lists prepared primarily for use in the Presbyterian Hospital, New York City. Among the lists included are the regular house diet for each day of the week, which includes the convalescent and soft diets, and typhoid, salt-poor, purin-free, gastric, diabetic, and other special diets. In the publication are also included a number of special recipes and miscellaneous tables.

Reports of the [Massachusetts] Commission on Cost of Living, R. Luce et al. ([Boston]: State, 1917, pp. 8+7+6+3+14).—This publication contains reports on anthracite coal, bread, the relation of transportation to prices, and department stores, and a final report which summarizes basic causes of the recent increase in prices, and the effect of the war, short crops, abnormal buying, inflation of currency, waste, etc., upon the cost of living. The report contains some recommendations.

Government control of food supplies in France (Mo. Rev., U. S. Bur. Labor Statis., 4 (1917). No. 4, pp. 525-533).—Information is given regarding the fixing of maximum prices for wheat, flour, bread, and other commodities; municipal and cooperative meat markets; the limitation of the sale and service of food, etc.

The interrelation between diet and body condition and the energy production during mechanical work in the dog, R. J. Anderson and G. Lusk (*Proc. Nat. Acad. Sci.*, 3 (1917), No. 5, pp. 386-389).—From the experimental data here reported, the following conclusions are drawn by the authors:

"The accomplishment of a given amount of mechanical work is always at the expense of a given amount of energy, and . . . the amount of energy required for mechanical work is independent of the physical condition of the subject and independent of the quantity of carbohydrate food present in the gastrointestinal tract. . . .

"Protein in the dietary is primarily for the repair of the tissues. It is not beneficial for the economical performance of work. In excess, it largely increases the heat production which a working organism is called on to eliminate.

"One may reduce the basal requirement for energy by starvation, and this process may economize food in the case of those who do no mechanical work.

"To accomplish a given amount of work a given amount of fuel energy is required, irrespective of the nutritive condition of the organism. This is of primary importance in the maintenance of armies or munition workers. Carbohydrate food fuel is utilized without loss."

The influence of the protein intake on the excretion of creatin in man, W. Denis and Anna S. Minot (Jour. Biol. Chem., 30 (1917), No. 1, pp. 47-51).—Ob-

servations upon five individuals suffering from Graves's disease showed that the amount of creatin excreted depended on the intake of protein. It was increased by high protein feeding and decreased by low protein feeding.

Inhibition of digestion of proteins by adsorbed tin, B. C. Goss (Jour. Biol. Chem., 30 (1917), No. 1, pp. 53-60, fig. 1).—This paper reports experiments in which artificial gastric and tryptic digestions of proteins were carried out in the presence and absence of adsorbed tin. The main object was to determine whether or not the stable tin-protein complex, formed by the adsorption of tin by foods having a high protein content, would pass through the body without being broken up by digestion.

It was found that "tin is readily adsorbed from solutions by coagulated proteins in amounts varying with the concentration according to the adsorption law of Freundlich. This adsorption takes place rapidly at first and then continues to increase slowly for several days, presumably because of the time required for diffusion into the solid. The adsorption complex is extremely stable and does not lose tin to a dilute acid or alkaline aqueous phase containing no tin, although the percentage of tin in the solid may be as high as 50 per cent. The presence of this tin, even in small amounts, interfered markedly with the digestion of the protein by either peptic or tryptic digestion, as was indicated by the change in color of the biuret reaction and by the visible retardation of the solution of coagulated proteins."

It appeared that it was only part of the protein, directly joined to the tin, whose digestion was hindered. "The effect of this retardation on the food value of a protein containing tin can only be a matter of conjecture, but it is probably small, since the total tin in foods rarely exceeds 0.03 per cent."

It was found that even after two days, in the case of artificial peptic digestions of the tin albumin containing 32 per cent of tin, there was no tin in a dialyzable form and only a very small amount in a filterable form, the latter probably being present as a colloid suspension of particles of the tin protein complex, split away from the solid by solution of the connecting albumin. "In the tryptic digestions no dialyzable tin was found in the liquor and only traces of filterable tin. Moreover, during digestion the percentage of tin in the solid rapidly increased, indicating that the protein which was not directly bound to the tin was being dissolved away."

The insoluble complex formed when coagulated proteins are brought into contact with solution containing tin was not broken up to any extent by artificial gastric and tryptic digestions. The author states that "while it is impossible to predict what the action of bacteria in the stomach and intestine would be, it is to be questioned whether the tin-protein complex is broken up in the actual digestive processes in the body and whether the tin which is combined in this way can have any toxic action."

Effect of ingestion of coffee, tea, and caffein on the excretion of uric acid in man, L. B. Mendel and Emma L. Wardell (Jour. Amer. Med. Assoc., 68 (1917), No. 24, pp. 1805-1807, fig. 1).—The authors review the literature of the physiological effect of caffein and report the results of a study undertaken to determine the effect of caffein ingestion upon the excretion of uric acid. The subject of the experiment received a purin-free diet and, after the endogenous level of uric acid excretion had been reached, a definite quantity of coffee infusion of known caffein content was added to the diet on each of five conscutive days. Experiments were also made with decaffeinated coffee, caffein, and tea.

The authors state that a modification of Benedict's method for determining uric acid made possible more accurate determinations than had hitherto been obtained.

The experiments showed that the addition of the strong coffee infusion to a purin-free diet caused a marked increase in the excretion of uric acid.

The addition of a commercial decaffeinated coffee to a purin-free diet did not cause any increase in the excretion of uric acid. If, however, caffein was added to this preparation the excretion of uric acid was increased decidedly, as was the case with coffee. The effect of adding tea to the purin-free diet was similar to that of adding coffee to the same diet. The increase in the quantity of uric acid excreted after the addition of coffee, tea, or caffein to the purin-free diet seemed to be proportional to the quantity of caffein ingested and was equal to the quantity of uric acid which would be obtained by the demethylation and subsequent oxidation of from 10 to 15 per cent of the ingested caffein.

The action of xanthin and methyl xanthins on the isolated intestine, W. SALANT and E. W. SCHWARTZE (*Proc. Soc. Expt. Biol. and Med.*, 14 (1916), No. 1, p. 15).

The action of succinate, malate, tartrate, and citrate on the isolated intestine, W. Salant, C. W. Mitchell, and E. W. Schwartze (*Proc. Soc. Expt. Biol. and Med.*, 14 (1916), No. 1, pp. 16, 17).

#### ANIMAL PRODUCTION.

How feed inspection helps the farmer, W. H. Strowd (Wisconsin Sta. Bul. 281 (1917), pp. 56, fig. 1).—Information with reference to feeding stuffs is summarized and analyses are given of cottonseed meal, cottonseed feed, linseed meal, gluten feed, corn oil meal, distillers' grains, hominy feed, corn feed meal, wheat bran, wheat middlings, red dog flour, germ middlings, oat middlings, rye middlings, rye bran, rye shorts, barley shorts, brewers' grains, malt sprouts, vinegar grains, alfalfa meal, bone meal, meat meal, meat scrap, tankage, dried beet pulp, screenings, and mixed and proprietary feeding stuffs.

How to feed live stock successfully, C. A. Willson (Tennessee Sta. Bul. 116 (1916), pp. 49-106, figs. 8; Col. Agr. Univ. Tenn., Ext. Div. Pub. 24 (1917). pp. 58, figs. 8.)—This popular treatise upon live-stock feeding discusses the traits of a successful feeder, principles to be considered in the feeding of farm animals, limitations as to the amounts of feed that should be given under various conditions, general rules for comparative valuations of feeding stuffs, balanced and standard rations, how to balance a ration, and the feeding of various kinds of live stock and poultry. The appendix gives in tabular form from sources already noted the average composition, digestible nutrients, and fertilizing constituents of American feeding stuffs, modified Wolff-Lehmann feeding standards, manurial values of farm products, fertility removed per acre by various farm crops, weights and measures of feeding stuffs, and suggested rations for beef and dairy cattle, horses, and mules.

How live stock is handled in the blue-grass region of Kentucky, J. H. Arnold (U. S. Dept. Agr., Farmers' Bul. 812 (1917), pp. 14).—This discusses the importance of knowing the best practice, what the blue-grass region farmer may do to increase his profits through live stock, utilization of waste products by means of animals, and feeding practice and cost of feed for different kinds of animals common on blue-grass farms, and presents analyses of the business on six individual farms. These farmers made beef cattle their leading stock enterprise, keeping sheep and hogs principally to utilize materials that otherwise would be wasted.

A study of the rate and economy of gains of fattening steers, H. W. Mumford, H. S. Grindley, A. D. Emmett, and S. Bull (Illinois Sta. Bul. 197 (1917).

pp. 567-604; abs. ed., pp. 3).—This bulletin reports results relating to the effect upon the rate and economy of gains of variations in the amount of feed consumed ranging from maintenance to full-feed rations, of variations in the proportions of roughage and concentrates in the ration, and of the substitution of a nitrogenous concentrate for a part of the grain in a ration of clover hay and ground corn in the ratio of 1:5.

The experiment reported lasted for 37 weeks and was divided into five test periods, the first of five weeks, the second, third, and fourth of six weeks, and the fifth four weeks in length. The animals used were 2-year-old choice feeder steers, four lots of four each. One lot was fed a ration slightly above maintenance; another, an amount of feed equal to the maintenance ration plus one-third of the difference between the maintenance and the full-feed rations; another an amount equal to the maintenance ration plus two-thirds of the difference between the maintenance and the full-feed rations; and another as much feed as the animals would eat readily. The rations of the first test period consisted of clover hay and ground corn in the ratio of 1:1; that of the second the same, in the ratio of 1:3; that of the third the same, in the ratio of 1:5; of the fourth and fifth, of clover hay, ground corn, and linseed meal in the ratio of 1:4:1.

The average daily gains per head for the entire experiment of 37 weeks were for the maintenance ration 0.7 lb., for the one-third additional ration 1.32 lbs., for the two-thirds additional ration 1.79 lbs., and for the full-feed ration 2.13 lbs. The variations for individual animals were for the respective lots 0.37-1.05, 1.23-1.39, 1.75-1.81, and 1.98-2.29 lbs. These averages include, however, data for two steers which were upon full feed from the thirty-first to the thirty-seventh week, inclusive.

Other data are shown in the following table:

Consumption of digestible dry substance and net energy per pound of gain.

Lot.	Dry substance.		Digestible dry sub- stance.		Net energy.	
	Average.	Variations.	Average.	Variations.	Average.	Variations.
One-third feed . Two-thirds feed Full feed.	Pounds. 1 9. 51 1 9. 40 9. 63	Pounds. 1 9. 17-10. 04 1 8. 95- 9. 64 8. 41-10. 47	Pounds.  1 6. 96  1 6. 67  6. 60	Pounds. 1 6. 73-7. 29 1 6. 48-6. 86 5. 95-7. 23	Therms. 17.22 16.90 6.73	Therms. 1 6, 97-7, 58 1 6, 67-7, 16 6, 10-7, 48

<sup>&</sup>lt;sup>1</sup> This average includes the data for two steers which were upon full feed from the thirty-first to the thirty-seventh week, inclusive.

It is concluded that "2-year-old steers may be maintained on 8 to 9 lbs. of dry substance, 0.39 to 0.44 lb. of digestible crude protein, and 6.5 to 6.8 therms of net energy per 1,000 lbs. live weight. Fattening 2-year-old steers may make satisfactory gains over a period of 37 weeks on 14.3 to 22.1 lbs. of dry substance, 0.72 to 1.44 lbs. of digestible crude protein, and 11.9 to 13 therms of net energy per 1,000 lbs. live weight. Fairly good gains may be made even on less amounts than these."

The rate of gains of 2-year-old steers is considered to depend upon the amount of feed consumed. "However, the amount of feed consumed between one-third feed and full feed apparently has no effect upon the economy of gains as measured by the consumption of feed, of total dry substance, of digestible dry substance, and of net energy per pound of gain."

When a ration consisting of clover hay and ground corn was changed to a similar ration in which the amounts of digestible dry substance and net

energy remained practically unchanged but the amount of protein was reduced from 10 to 12 per cent the rate of economy of gains was considerably decreased. A decrease was also observed where there was a change to a ration in which the digestible dry substance, digestible protein, and energy were slightly reduced. The substitution of the linseed meal in the fifth feeding period materially increased the rate of gains and the economy of gains.

"Steers which have been kept on a low plane of nutrition (maintenance) for a considerable time make more economical gains when put upon a full-feed ration than steers which have been upon full feed for some time. However, steers receiving more than a maintenance but less than a full-feed ration make no more economical gains when put upon full feed than steers which have already been on full feed."

The investigation indicates that "steers may be maintained or fattened with the ordinary rations of the corn belt on less digestible dry matter, on less digestible protein, and on less net energy than the amounts prescribed by the generally accepted feeding standards."

Information for horse breeders, L. L. Lewis and W. P. Shuler (Oklahoma Sta. Circ. 43 (1917), pp. 11, fig. 1).—This circular gives in concise form information for persons engaged in horse raising. The topics discussed include artificial insemination, some diseases of the reproductive organs of mares and stallions, and the general care of mares and foals.

Preserving eggs for the home, B. Alder (*Utah Sta. Circ. 25 (1917*), pp. 8).—This circular briefly reviews recent experiments on the preservation of eggs and gives directions for the home preservation of eggs in limewater and water glass.

In tests at the station 12 doz. eggs were placed in a crock jar and covered with a 10 per cent solution of water glass on April 1, 1913. During the following winter some of these eggs were tested and found to be in very good condition. Some of them were kept in the solution until the latter part of June, 1914, when most of the eggs retained a fairly fresh appearance as far as ordinary observation could determine. There was no change in the size of the air cell.

In similar tests conducted more recently the quality of the eggs deteriorated rather rapidly after about eight or ten months of storage. During the last two years water glass and a patented preservative for coating eggs have been compared. Good results were obtained with each method, but after five or six months of storage the eggs preserved with the patented preservative deteriorated the more rapidly.

#### DAIRY FARMING-DAIRYING.

Selecting dairy bulls by performance, W. E. CABROLL (*Utah Sta. Bul. 153* (1917), pp. 3-19, figs. 3).—The author discusses the selection of dairy sires by performance, which in the sense here used is meant the ability of the sire to transmit to his daughters the potentiality of high milk and fat production.

Results are given of a study of standards of measuring performance or comparative value of dairy bulls. The data reported consist of seven-day milk and fat production records taken from the Holstein-Friesian Yearbook. Only bulls having 50 or more A. R. O. daughters were considered. The 32 bulls whose progeny were studied have to their credit a total of 2,579 tested daughters and 1,052 proved sons, who in turn have 7,632 tested daughters, making a total of 10,211 individual milk-fat records, as every tested daughter of each bull was considered in the study. The records are classified by age groups, and they show that these cows exceeded the present association age requirements by

averages of from 64.8 per cent in the junior three-year-old group to 48.3 per cent in the aged cow group. Revised Advanced Registry requirements are calculated from the actual average fat production of cows in the different age groups based on 12 lbs. for an aged cow—the present aged requirement. Except for the aged cows, the revised standard is higher for all age groups than the present standard.

The A. R. O. fat production record of every daughter of each sire is reduced to a percentage of the association requirements, and the averages of these percentages for the daughters of each bull are considered the comparative values of the bulls as revealed by the performance of their A. R. O. daughters. Of the 32 bulls compared on this basis King of the Pontiacs heads the list, having 149 A. R. O. daughters, with an average percentage value of 186.4; King Segis stands second, with a value of 181.2 per cent; and Lord Netherland De Kol stands lowest among the 32, with an average value of 133.9 per cent. When compared on the basis of the number of A. R. O. daughters Lord Netherland De Kol, who has 122 such daughters, is exceeded only by King of the Pontiacs. The 32 sires are also compared on the basis of percentage performance of their A. R. O. daughters based on the revised age requirements above mentioned. No very great differences occur in the relative standing of the sires when compared on the two bases.

An attempt was also made to obtain a measure of the performance of a bull by the performance of his sons. To this end the records of the 7,632 daughters of the sons of the bulls in question were calculated to a percentage basis, as outlined above, these records being taken as a measure of the son's performance. The correlation coefficient between the average value of bulls and the average value of sons of these same bulls as shown by the average percentage values of their daughters is 0.6326±0.0715. This high correlation is not considered evidence that fat production is transmitted through the male line.

The method suggested by the author of testing out a new sire is to "breed him only to a few older cows of known breeding capacity, then hold him in reserve, using him only when absolutely necessary, till the results of this first trial are completed. If the majority of these first heifers prove to be satisfactory producers, the bull could then safely be used generally in the herd; if not, he should be discarded."

Cow-testing associations, E. M. Clark (Illinois Sta. Circ. 196 (1917), pp. 10, figs. 2).—Brief information is given on the advantages of cooperative cowtesting associations, including hints on their formation and operation.

Feeding dairy cattle, A. C. McCandlish (*lowa Sta. Circ. 34 (1917)*, pp. 32).—This popular treatise deals with the subject under the headings of constituents of feeds, functions of nutrients, definitions and characteristics of feeds, requirements of a ration, and the feeding of dairy animals.

Studies in the cost of market milk production, A. C. Anderson and F. T. Riddle (Michigan Sta. Bul. 277 (1916), pp. 38, figs. 9).—Data are presented on the cost of producing milk for the city market on 29 farms in the territory of the Grand Rapids Milk Producers' Association. These data cover the years 1914 and 1915, 25 farms being studied each year, and one of the authors spending his entire time on the farms.

On all of the farms where the investigations were carried on the production of milk was only one of the enterprises of the farm. On a few of them it was practically the sole enterprise, and crops were grown simply to feed the herd. On other farms milk production was coupled with grain, vegetables, live stock, or fruit production for the market. None of these other enterprises were considered in any manner.

The average number of cows per year on the 25 farms was 459.46 in 1914 and 428.57 in 1915. The average daily labor requirement per cow when all the cows are considered was 28.73 minutes in 1914 and 28.56 minutes in 1915. The average yearly feed cost per cow varied from \$39.27 to \$93.54 on the different farms, the general average for the two years being \$65.24. Of this amount the average charge for pasture was \$7.98 per year. The total expenses per cow in 1914 were \$150.57, and in 1915, \$150.29. Of these amounts 30 per cent was for labor, 45 per cent for feed, and 25 per cent for overhead charges. The total value of products per cow was \$158.80 in 1914 and \$156.60 in 1915. The average milk yield per cow was 6,928 lbs. in 1914 and 7,156.8 lbs. in 1915. The cost of production and delivery of milk per hundredweight was \$1.916 in 1914 and \$1.854 in 1915. The net profit on milk was 1 ct. per gallon in 1914 and 0.7 ct. in 1915.

According to the data obtained in this study, 72 per cent of the dairies were profitable and 28 per cent were operated at a loss. In discussing conditions under which these profits and losses were brought about, it is stated that "no one factor seems to determine a profit or loss. In some cases high producing herds have failed to be remunerative, while in others very low producing herds have made a profit. The cost of labor, feeds, and the investment, as well as the system of management of the business, are important factors. Losses due to tuberculosis played a very important part in raising the cost of milk, and since these losses are occasioned by and sustained wholly in compliance with city ordinance, it is eminently fair and equitable that the producer should receive sufficient compensation for his improved product to safeguard him against losses from this source. Buildings poorly arranged, hauling feed and milk in small quantities for long distances, and the maintaining of low-producing cows tend to raise the cost of production. Moderate investment in buildings and equipment, systematized labor, moderate-priced feeds, and high-producing cows are inducive to profits. On the other hand, the price received for the product determines a profit or loss when milk is produced under economical conditions. The price secured should be great enough to allow a fair margin of profit."

A summation of the receipts and expenditures of each of the dairies under investigation for each year and other data brought out in the investigations are presented in graphic charts and diagrams.

Clarification of milk, T. J. McInerney (New York Cornell Sta. Bul. 389 (1917), pp. 487-504, figs. 7).—The author briefly reviews the history of clarification studies, and gives detailed results of experimental work the object of which was to determine the advantages and disadvantages of the clarifier in commercial work. The points studied were the effect of clarification on the germ content and chemical and physical qualities of milk. In the experiments samples of milk were examined immediately before and after clarifying. The germ content was determined by the plate method, the total solids by the chemical method, and the fat content by the Babcock method. The acidity was determined by titrating 18 gm. of the sample with a tenth-normal alkali solution. The amount of insoluble dirt was determined by filtering equal quantities of clarified and unclarified milk through absorbent cotton. The amount of cream rising was determined by filling graduated, straight-sided cylinders with the samples and allowing them to stand for 24 hours. The keeping quality was determined by holding samples of clarified and of unclarified milk at definite temperatures and noting the time required for the milk to curdle.

An average increase in the bacterial content of milk due to clarification in these experiments was noted of 87.15 per cent in the case of fresh milk and

114.77 per cent in the case of old milk. "Bacteria increase more rapidly in unclarified milk than in clarified milk. The fat content before and after clarification is practically the same. The percentage of total solids is slightly reduced by clarification. This is probably due to the slime removed. The development of acidity is slightly more rapid in clarified milk than in unclarified milk. The keeping quality of milk remains about the same after clarification as it was before. About 99 per cent of the insoluble dirt in milk is removed by clarification. The volume of cream that is separated by gravity is reduced from 2 to 3 per cent by clarification. This is probably due to the agitation of the milk in passing through the clarifier."

Average analyses of eight samples of clarifier slime show the following percentage composition: Water 71.33, total solids 28.67, nitrogen 0.33, casein 2.13, fat 4, and ash 3.15.

A bibliography of 18 titles is given.

Pasteurization of cream, C. Labsen, J. M. Fuller, V. R. Jones, H. Gregory, and M. Tolstrup (South Dakota Sta. Bul. 171 (1916), pp. 529-548, flgs. 6).— The objects of the experiments reported in this bulletin were to determine the efficiency and practicability of the coil cream vat as a cream pasteurizer in the manufacture of butter, the effectiveness of different temperatures of cream pasteurization, and also the keeping properties of the butter made from the cream pasteurized at the different temperatures. The cream used in the experiments was obtained from the regular college creamery patrons and contained about 30 per cent of fat.
